DESCRIPTION

The MP5011 is a device designed to protect circuitry on the output (source) from transients on the input (V_{CC}). It also protects the input from undesirable shorts and transients coming from the source.

At start up, the limited slew rate at the source limits the inrush current. A small capacitor at the dv/dt pin controls this slew rate. The dv/dt pin has an internal circuit that allows the customer to float this pin and still achieve a 1.4ms ramp time at the source.

The maximum load at the output is current-limited by using a sense MOSFET topology. An external resistor from the I-LIMIT pin to the source pin controls the magnitude of the current limit.

An internal charge pump drives the gate of the power device, allowing for the use of a DMOS power MOSFET with an ON resistance of just 44mΩ.

The device also includes protective features to protect the source against an input voltage that is outside the operating range.

FEATURES

- Integrated 44mΩ Power MOSFET
- Enable/Fault Pin
- Adjustable Slew Rate for Output Voltage
- Adjustable Current Limit: 1A-5A
- Thermal Protection
- Over-Voltage Protection

APPLICATIONS

- Hot Swap
- PC Cards
- Laptops

All MPS parts are lead-free and adhere to the RoHS directive. For MPS green status, please visit MPS website under Quality Assurance. "MPS" and "The Future of Analog IC Technology" are Registered Trademarks of Monolithic Power Systems, Inc.

V_{CC}, SOURCE, I-LIMIT Transient (100ms)…25V
dv/dt, ENABLE/FAULT.................... -0.3V to 6V
Storage Temperature............... -65°C to +155°C
Continuous Power Dissipation   ($T_A = 25°C$) [2]
....2.5W
Operating Junction Temperature   -40°C to 150°C

Recommended Operating Conditions [3]

Supply Voltage V_{IN} .... 9V to 15V
Maximum Junction Temp. (T_J) .... 125°C

Thermal Resistance [4] $θ_{JA}$ $θ_{JC}$

QFN10 (3x3mm).....................50 ...... 12 ...°C/W

Notes:
1) Exceeding these ratings may damage the device.
2) The maximum allowable power dissipation is a function of the maximum junction temperature $T_J(MAX)$, the junction-to-ambient thermal resistance $θ_{JA}$, and the ambient temperature T_A. The maximum allowable continuous power dissipation at any ambient temperature is calculated by $P_D(MAX)=(T_J(MAX)-T_A)/ θ_{JA}$. Exceeding the maximum allowable power dissipation will cause excessive die temperature, and the regulator will go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
3) The device is not guaranteed to function outside of its operating conditions.
4) Measured on JESD51-7 4-layer board.

ELECTRICAL CHARACTERISTICS

V_{CC} = 12V, R_{LIMIT}=15.4Ω, Capacitive Load = 100µF, T_A=25°C, unless otherwise noted.

Parameters	Symbol	Condition	Min	Typ	Max	Units
Power FET						
Delay Time	t_{DLY}	Enabling of chip to I_D=100mA with a 1A resistive load	0.1	0.15	0.2	ms
ON Resistance [5]	R_{DSon}	T_J=25°C		44	55	mΩ
		T_J=80°C		52

Low-Level Input Current (Sink)	I_{IL}	V_{ENABLE}=0V		-28	-50	µA
Maximum Fanout for Fault Signal		Total number of chips that can be connected for simultaneous shutdown			3	Units
Maximum Voltage on Enable/Fault Pin [7]	V_{MAX}				VCC	V
Total Device						
Bias Current	I_{BIAS}	Device Operational		1.5	2.0	mA
		Thermal Shutdown		0.4		
Minimum Operating Voltage for UVLO	V_{MIN}	Enable<0.5V			5	V

Notes:
5) Guaranteed by design.
6) Measured from 10% to 90%.
7) Maximum Input Voltage on Enable pin to be ≤ 6.0V if Vcc ≥ 6.0V, Maximum Input Voltage on Enable pin to be Vcc if Vcc ≤ 6.0V.

PIN FUNCTIONS

| Pin #	Name	Description
1	GND	Negative Input Voltage to the Device. This is used as the internal reference for the IC.
2	dv/dt	Slew Rate control. The internal dv/dt circuit controls the slew rate of the output voltage at turn-on. An internal capacitor allows the voltage to ramp up over 1.4ms. Use an external capacitor to increase the ramp time. If an additional time delay is not required, leave this pin open.
3	Enable/Fault	The Enable/Fault pin. A tri-state, bi-directional interface. It enables the output of the device when left floating, or disables the device when pulled to ground using an open-drain or open-collector device. In the event of a thermal fault, the voltage enters an intermediate state to signal a monitoring circuit that the device is in thermal shutdown. See text: "ENABLE/FAULT PIN".
4	I-Limit	Overload and Short-Circuit Current Set. Use a resistor between this pin and the Source pin to set the overload and short-circuit current limit levels.
5	NC	DO NOT CONNECT. Pin must be left floating.
6-10	SOURCE	Output. This pin is the source of the internal power FET and the output terminal of the IC.
Exposed Pad	V_{CC}	Positive Input Voltage.

BLOCK DIAGRAM

Figure 1: Functional Block Diagram

OPERATION

Current Limit

The current limit is a function of the external current limit resistor.
**Table 1: Current Limit vs. Current Limit Resistor (VCC=12V)**

Current Limit Resistor (Ω)	15.4	50	100
Trip Current (A)	5.3	3.4	2.8
Hold Current (A)	4.5	2.1	1.2

If a short is present or the load reaches the trip current—the minimum threshold current to trigger over-current protection (OCP)—when the part is active, the part switches into to a constant-current (hold) mode (CCM). The device shuts down only if the over-current condition remains for long enough to trigger thermal protection.

However, when the part is powered up by V_{CC} or EN, the load current should be smaller than the current. Otherwise, the part will not completely turn on.

In a typical application using a current limit resistor of 15.4Ω, the trip current is 5.3A and the hold current is 4.5A. If the device is in its normal operating state and passing 2.0A it will need to dissipate only 176mW with a very low ON resistance of 44mΩ. For a package dissipation of 50°C/Watt, the temperature rise will only be +9°C; with 25°C ambient temperature, this amounts to a total package temperature of 34°C.

In the case of a short-circuit condition, the device now has 12V across it and the hold current clamps at 4.5A and therefore must dissipate 44W. At 50°C/watt, the temperature rises above the MP5011 thermal protection (175°C) if left unchecked and device shutdown allows the temperature to drop below a hysteresis level. Use an appropriate heat sink if the device is intended to supply the hold current and not shutdown. Without a heat sink, maintain the hold current below 250mA at 25°C and below 150mA at 85°C to prevent the device from activating the thermal shutdown feature.

Figure 2

Rise Time

The rise time is a function of the capacitor ($C_{dv/dt}$) on the dv/dt pin.

Table 2: Rise Time vs. $C_{dv/dt}$

$C_{dv/dt}$	None	33pF	470pF	1nF
Rise Time (Typ) (ms)	1.4	2.0	11.6	22.5

* **Notes:** Rise Time = K_{RT}*($50pF+C_{dv/dt}$), K_{RT} =22E6

The rise time is measured by from 10% to 90% of output voltage.

Figure 3

Enable / Fault Pin

The Enable/Fault pin is a bi-directional, three-level I/O with a weak pull-up current (typically 25µA). There are three levels: low, mid, and high. It enables/disables the part and relays fault information.

When the Enable/Fault pin is an input:

1. Low and mid levels disable the part.

2. Low clears the fault flag in addition to disabling the part.

3. High enables the part (if the fault flag is clear).

When the Enable/Fault pin is an output:

1. The pull-up current (if not overridden) allows for a "wired NOR" pull up to enable the part.

2. An under-voltage causes a low on the Enable/Fault pin, and clears the fault flag. A thermal fault causes a mid level on the Enable/Fault pin, and sets the fault flag.

The Enable/Fault line must be above the mid level for the output to be turned on.

The fault flag is an internal flip-flop that can be set or reset under various conditions:

1. Thermal Shutdown: set fault flag

2. Under-Voltage: reset fault flag

3. Low Voltage on Enable/Fault Pin: reset fault flag

4. Mid Voltage on Enable/Fault Pin: no effect

Under a fault, the Enable/Fault pin goes to the mid level.

There are four types of faults, and each fault has a direct and indirect effect on the Enable/Fault pin and the internal fault flag.

In a typical application there are one or more MP5011 chips in a system. Typically, tie the Enable/Fault lines together.

Table 3: Fault Function Influence in Application

Fault description	Internal action	Effect on Fault Pin	Effect on Flag	Effect on secondary Part
Short/Over Current	Limit current	none	None	none
Under-Voltage	Output turns off	Internally drives Enable/Fault pin to Logic low	Flag resets	Secondary part output disabled, and fault flag resets.
Over-Voltage	Limit output voltage	None	None	None
Thermal Shutdown	Shutdown part. The part is latched off until a UVLO or externally driven to ground.	Internally drives Enable/Fault pin to mid level	Flag sets	Secondary-part output disabled.

Under-Voltage Lockout Operation

If the supply (input) is below the UVLO threshold, the output is disabled, and the fault line is driven low.

When the supply goes above the UVLO threshold, the output is enabled and the fault line releases. When the fault line releases, a 25µA current source pulls it high without the need for an external pull up resistor. The pull-up voltage has a 5V limit.
Thermal Protection

In the presence of a thermal protection fault, the output is disabled and the fault line is driven to the mid level. The thermal fault condition latches—the fault flag is set—and the part remains latched off until the fault (enable) line goes low. Cycling the power below the UVLO threshold also resets the fault flag.
10

PCB LAYOUT

Please follow these guidelines use Figure 4 below figure reference to design for stable operation:

- Place R$_{limit}$ close to the I$_{\_Limit}$ pin, C$_{dv/dt}$ close to the dv/dt pin and the input capacitor close to the V$_{CC}$ pin.

- Float the NC pin.

- Add vias for the thermal pad and use a large copper surfaces for V$_{CC}$ and source to achieve better thermal performance.
