256Mb/512Mb/1Gb SEMPER™ Flash

Quad SPI, 1.8V/3.0V

Features

- CYPRESS™ 45-nm MIRRORBIT™ technology that stores two data bits in each memory array cell
- Sector architecture options
 - Uniform: Address space consists of all 256KB sectors
 - Hybrid Configuration 1: Address space consists of thirty-two 4KB sectors grouped either on the top or the bottom while the remaining sectors are all 256KB
 - Hybrid Configuration 2: Address space consists of thirty-two 4KB sectors equally split between top and bottom while the remaining sectors are all 256KB
- Page programming buffer of 256 or 512 bytes
- OTP secure silicon array of 1024 bytes (32 × 32 bytes)
- Quad SPI
 - Supports 1S-1S-4S, 1S-4S-4S, 1S-4D-4D, 4S-4S-4S, 4S-4D-4D protocols
 - SDR option runs up to 83-Mbps (166MHz clock speed)
 - DDR option runs up to 102-Mbps (102MHz clock speed)
- Dual SPI
 - Supports 1S-2S-2S protocol
 - SDR option runs up to 41.5-Mbps (166MHz clock speed)
- SPI
 - Supports 1S-1S-1S protocol
 - SDR option runs up to 21-Mbps (166MHz clock speed)
- Functional safety features
 - Functional safety with the industry's first ISO26262 ASIL B compliant and ASIL D ready NOR Flash
 - Infineon® Endurance Flex architecture provides high-endurance and long retention partitions
 - Data integrity CRC detects errors in memory array
 - SafeBoot reports device initialization failures, detects configuration corruption, and provides recovery options
 - Built-in error correcting code (ECC) corrects single-bit error and detects double-bit error (SECDED) on memory array data
 - Sector erase status indicator for power loss during erase
- Protection features
 - Legacy block protection for memory array and device configuration
 - Advanced sector protection for individual memory array sector based protection
- AutoBoot enables immediate access to the memory array following power-on
- Hardware reset through CS# Signaling method (JEDEC) / individual RESET# pin / DQ3_RESET# pin
- Serial flash discoverable parameters (SFDP) describing device functions and features
- Device identification, manufacturer identification, and unique identification
- Data Integrity
 - 256Mb devices
 - Minimum 640,000 program-erase cycles for the main array
 - 512Mb devices
 - Minimum 1,280,000 program-erase cycles for the main array
 - 1Gb devices
 - Minimum 2,560,000 program-erase cycles for the main array
 - All devices
 - Minimum 300,000 program-erase cycles for the 4KB sectors
 - Minimum 25 Years data retention

Data integrity

Data integrity

Program / Erase (PE) endurance - High endurance (256KB sectors)

Sectors in partition	Minimum PE cycles	Minimum retention time	Unit
512 (Default for 1GB devices)	2,560,000		
508	2,540,000		
504	2,520,000		
256 (Default for 512MB devices)	1,280,000		
252	1,260,000	2	Years
128 (Default for 256MB devices)	640,000		
28	140,000		
24	120,000		
20	100,000		

Note Minimum cycles is for entire high endurance partition.

Program / Erase endurance - Long retention partition (256KB sectors)

Minimum PE cycles	Minimum retention time	Unit		
500	25	Years		

Note Minimum cycles is for each sector.

Program / Erase endurance 4KB sector and nonvolatile register array

Flash memory type	Minimum cycles	Unit	Minimum retention time	Unit
	500		25	
Program/Erase cycles per 4KB sector	300,000 Note It is required to restrict the power loss events to 300 times per sector during program or erase operation to achieve the mentioned endurance cycles.	PE cycles	2	Years
Program/Erase cycles per persistent protection bits (PPB) array or nonvolatile register array Note Each write transaction to a nonvolatile register causes a PE cycle on the entire nonvolatile register array.	500	, 2 6, 6,66	25

Pinout and signal description

Signal description Table 1

ianie 1	Jigilal desc	iiptioii	
Symbol	Туре	Mandatory / optional	Description
CS#	Input	Mandatory	Chip Select (CS#). All bus transactions are initiated with a HIGH to LOW transition on CS# and terminated with a LOW to HIGH transition on CS#. Driving CS# LOW enables the device, placing it in the active mode. When CS# is driven HIGH, the device enters standby mode, unless an internal embedded operation is in progress. All other input pins are ignored and the output pins are put in high impedance state. On parts where the pin configuration offers a dedicated RESET# pin, it remains active when CS# is HIGH.
СК	Input	Mandatory	Clock (CK). Clock provides the timing of the serial interface. Transactions are latched on the rising edge of the clock. In SDR protocol, command, address and data inputs are latched on the rising edge of the clock, while data is output on the falling edge of the clock. In DDR protocol, command, address and data inputs are latched on both edges of the clock, and data is output on both edges of the clock.
DQ0/SI	Input/Output	Mandatory	Serial Input (SI) for single SPI protocol DQ0 Input/ Output for Dual or Quad SPI protocol
DQ1/SO	Input/Output	Mandatory	Serial Output (SO) for single SPI protocol DQ1 Input/ Output for Dual or Quad SPI protocol
DQ2 / WP#	Input/Output (weak Pull-up)	Mandatory	Write Protect (WP#) for single and dual SPI protocol DQ2 Input/ Output for Quad SPI protocol The signal has an internal pull-up resistor and can be left unconnected in the host system if not used for Quad transactions or write protection. If write protection is enabled, the host system is required to drive WP# HIGH or LOW during write register transactions.
DQ3 / RESET#	Input/Output (weak Pull-up)	Mandatory	RESET# for single and dual SPI protocol. This signal can be configured as RESET# when CS# is HIGH or Quad SPI protocol is disabled. DQ3 Input/ Output for Quad SPI protocol The signal has an internal pull-up resistor and can be left unconnected in the host system if not used for Quad SPI transactions or RESET#
RESET#	Input (weak Pull-up)	Optional	Hardware Reset (RESET#). When LOW, the device will self initialize and return to the array read state. DQ[3:0] are placed into the high impedance state when RESET# is LOW. RESET# includes a weak pull-up, meaning, if RESET# is left unconnected it will be pulled up to the HIGH state on its own.
V _{CC}	Power Supply	Mandatory	Core Power Supply
V _{SS}	Ground Supply	Mandatory	Core Ground
DNU	-	-	Do Not Use.

2 Interface overview

2.1 General description

The CYPRESS™ SEMPER™ Flash with Quad SPI family of products are high-speed CMOS, MIRRORBIT™ NOR Flash devices. SEMPER™ Flash is designed for Functional Safety with development according to ISO 26262 standard to achieve ASIL-B compliance and ASIL-D readiness.

SEMPER™ Flash with Quad SPI devices support traditional SPI single bit serial input and output, optional two bit (Dual I/O or DIO) as well as four bit wide Quad I/O (QIO) and Quad Peripheral Interface (QPI) protocols. In addition, there are DDR read transactions for QIO and QPI that transfer address and read data on both edges of the clock.

Read operations from the device are burst oriented. Read transactions can be configured to use either a wrapped or linear burst. Wrapped bursts read from a single page whereas linear bursts can read the whole memory array.

The erased state of each memory bit is a logic 1. Programming changes a logic 1 (HIGH) to a logic 0 (LOW). Only an erase operation can change a memory bit from a 0 to a 1. An erase operation must be performed on a complete sector (4KBs or 256KBs).

SEMPER™ Flash provides a flexible sector architecture. The address space can be configured as either a uniform 256KB sector array, or a hybrid configuration 1 where thirty-two 4KB sectors are either grouped at the top or at the bottom while the remaining sectors are all 256KB, or a hybrid configuration 2 where the thirty-two 4KB sectors are equally split between the top and the bottom while the remaining sectors are all 256KB.

The Page Programming Buffer used during a single programming operation is configurable to either 256 bytes or 512 bytes. The 512 byte option provides the highest programming throughput.

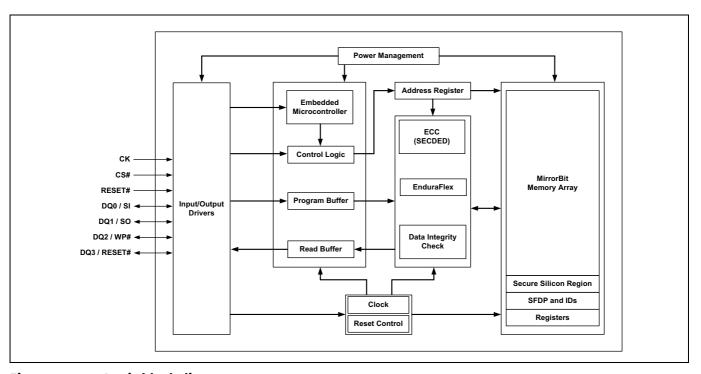

Figure 4 Logic block diagram

The SEMPER™ Flash with Quad SPI family consists of multiple densities with, 1.8V and 3.0V core and I/O voltage options.

Quad SPI, 1.8V/3.0V

Interface overview

The device control logic is subdivided into two parallel operating sections: the Host Interface Controller (HIC) and the Embedded Algorithm Controller (EAC). The HIC monitors signal levels on the device inputs and drives outputs as needed to complete read, program, and write data transfers with the host system. The HIC delivers data from the currently entered address map on read transfers; places write transfer address and data information into the EAC command memory, and notifies the EAC of power transition, and write transfers. The EAC interrogates the command memory, after a program or write transfer, for legal command sequences and performs the related Embedded Algorithms.

Changing the nonvolatile data in the memory array requires a sequence of operations that are part of Embedded Algorithms (EA). The algorithms are managed entirely by the internal EAC. The main algorithms perform programming and erase of the main flash array data. The host system writes command codes to the flash device. The EAC receives the command, performs all the necessary steps to complete the transaction, and provides status information during the progress of an EA.

Executing code directly from flash memory is often called Execute-In-Place (XIP). By using XIP with SEMPER™ Flash devices at the higher clock rates with Quad or DDR Quad SPI transactions, the data transfer rate can match or exceed traditional parallel or asynchronous NOR Flash memories while reducing signal count dramatically.

Infineon® Endurance Flex architecture provides system designers the ability to customize the NOR Flash endurance and retention for their specific application. The host defines partitions for high endurance or long retention, providing up to 1+ million cycles or 25 years of data retention.

The SEMPER™ Flash with Quad SPI device supports error detection and correction by generating an embedded Hamming error correction code during memory array programming. This ECC code is then used for single-bit and double-bit error detection and single-bit correction during read.

The SEMPER™ Flash with Quad SPI device has built-in diagnostic features providing the host system with the device status.

- Program and Erase Operation: Reporting of program or erase success, failure and suspend status
- Error Detection and Correction: 1-bit and/or 2-bit error status with address trapping and error count
- Data Integrity Check: Error detection over memory array contents
- SafeBoot: Reporting of proper flash device initialization and configuration corruption recovery
- Sector Erase Status: Reporting of erase success or failure status per sector
- Sector Erase Counter: Counts the number of erase cycles per sector

2.2 Signal protocols

2.2.1 SEMPER™ Flash with Quad SPI clock modes

The SEMPER™ Flash with Quad SPI device can be driven by an embedded microcontroller (bus master) in either of the following two clocking modes:

- Mode 0 with Clock Polarity LOW at the fall of CS# and staying LOW until it goes HIGH at capture input.
- Mode 3 with Clock Polarity HIGH at the fall of CS# then going LOW to HIGH at capture input.

For these two modes, data is latched into the device on the rising edge of the CK signal in SDR protocol and both edges of the CK signal in DDR protocol. The output data is available on the falling edge of the CK clock signal. For DDR protocol, Mode 3 is not supported.

The difference between the two modes is the clock polarity when the bus master is in Standby mode and not transferring any data.

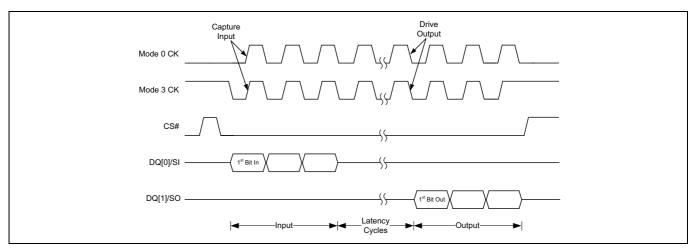

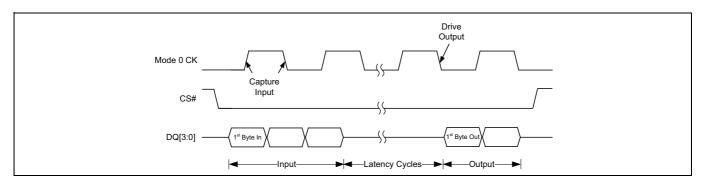

Figure 5 **SPI SDR mode support**

SPI DDR mode support Figure 6

256Mb/512Mb/1Gb SEMPER™ Flash Quad SPI, 1.8V/3.0V

Interface overview

2.3 Transaction protocol

Transaction

- During the time that CS# is active (LOW) the clock signal (CK) is toggled while command information is first transferred on the data (DQ) signals followed by address and data from the host to the flash device. The clock continues to toggle during the transfer of read data from the flash device to the host or write data from the host to the flash device. When the host has transferred the desired amount of data, the host drives the CS# inactive (HIGH). The period during which CS# is active is called a transaction on the bus.
- While CS# is inactive, the CK is not required to toggle.
- The command transfer occurs at the beginning of every transaction. The address, latency cycles, and data transfer phases are optional and their presence depends on the protocol mode or command transferred.

Transaction capture

• CK marks the transfer of each bit or group of bits between the host and memory. Command, address and write data bits transfer occurs on CK rising edge in SDR transactions, or on every CK edge, in DDR transactions.

NoteAll attempts to read the flash memory array during a program or erase (embedded operations) are ignored. The embedded operation will continue to execute without any effect. A very limited set of commands are accepted during an embedded operation. These are discussed in **Suspend and resume embedded operation on page 61.**

Protocol terminology

• The number of DQ signals used during the transaction, depends on the current protocol mode or command transferred. The latency cycles do not use the DQ signals for information transfer. The protocol mode options are described by the data rate and the DQ width (number of DQ signals) used during the command, address, and data phases in the following format:

WR-WR-WR, where:

- The first WR is the command bit width and rate.
- The second WR is the address bit width and rate.
- The third WR is the data bit width and rate.
- The bit width value may be 1, 2 or 4. R has a value of S for SDR or D for DDR. SDR has the same transfer value during the rising and falling edge of a clock cycle. DDR can have different transfer values during the rising and falling edges of each clock.
- Examples:
 - 1S-1S-1S means that the command is 1 bit wide SDR, the address is 1 bit wide SDR, and the data is one bit wide SDR.
 - 4S-4D-4D means that the command is 4 bits wide SDR, address, and data transfers are 4 bits wide DDR.

Protocols definition

- Protocol Modes defined for the SEMPER™ Flash with Quad SPI:
- 1. 1S-1S-1S: One DQ signal used during command transfer, address transfer, and data transfer. All phases are SDR.
- 2. 1S-2S-2S: One DQ signal used during command transfer, two DQ signals used during address transfer, and data transfer. All phases are SDR.
- 3. 1S-1S-4S: One DQ signal used during command and address transfer, four DQ signals used during data transfer. All phases are SDR.
- 4. 1S-4S-4S: One DQ signal used during command transfer, four DQ signals used during address transfer, and data transfer. All phases are SDR.
- 5. 1S-4D-4D: One DQ signal used during command transfer at SDR, four DQ signals used during address and data transfer at DDR.
- 6. 4S-4S-4S: Four DQ signals used during command transfer, address transfer, and data transfer. All phases are SDR.

Quad SPI, 1.8V/3.0V

Interface overview

infineon

7. 4S-4D-4D: Four DQ signals used during command transfer at SDR, four DQ signals used during address and data transfer at DDR.

- Each transaction begins with an 8-bit (1-byte) command. The command selects the type of information transfer or device operation to be performed.
- All protocols supports 3 or 4-byte addressing.

1S-1S-1S protocol (single input/output, SIO)

- The 1S-1S-1S mode is the preferred default protocol following Power-on-Reset (POR), but flash devices can be configured to reset into the Quad mode.
- This protocol uses DQ[0]/SI to transfer information from host to flash device and DQ[1]/SO to transfer information from flash device to host. On each DQ, information is placed on the DQ line in Most Significant bit (MSb) to Least Significant bit (LSb) order within each byte. Sequential address bytes are transferred in highest order to lowest order sequence. Sequential data bytes are transferred in lowest address to highest address order.
- In 1S-1S-1S, DQ[3:2] are not used for data transfer period. DQ[2] can be used as a WP# and DQ[3] can be used as a RESET# input. Otherwise, the DQ[3:2] signals will be high impedance.

1S-2S-2S protocol (dual input/output, DIO)

- This protocol uses DQ[1:0] signals. The 8-bit command placed on the DQ[0] in MSb to LSb order. The LSb of address byte is placed on DQ[0] with next order bit on DQ[1] signal ans so on. Sequential address bytes are transferred in highest order to lowest order sequence. Sequential data bytes in SDR are transferred in lowest address to highest address order.
- In 1S-2S-2S, DQ[3:2] are not used for data transfer period. DQ[2] can be used as a WP# and DQ[3] can be used as a RESET# input. Otherwise, the DQ[3:2] signals will be high impedance.

1S-1S-4S protocol (quad output read, QOR)

• This protocol uses DQ[3:0] signals. The 8-bit command and address placed on the DQ[0] in MSb to LSb order. Sequential data bytes in SDR are transferred in lowest address to highest address order.

1S-4S-4S and 1S-4D-4D protocol (quad input/output, QIO)

• This protocol uses DQ[3:0] signals. The 8-bit command placed on the DQ[0] in MSb to LSb order. The LSb of address byte is placed on DQ[0] with each higher order bit on the successively higher numbered DQ signals. Sequential address bytes are transferred in highest order to lowest order sequence. Sequential data bytes in SDR are transferred in lowest address to highest address order. Sequential data bytes in DDR are transferred only in byte pairs (words) where the byte order depends on the order in which the bytes are written or programmed in that protocol mode. Sequential data bytes are transferred in lowest address to highest address order.

4S-4S-4S and 4S-4D-4D protocol (quad peripheral interface, QPI)

• This protocol uses DQ[3:0] signals. The LSb of each byte is placed on DQ[0] with each higher order bit on the successively higher numbered DQ signals. Sequential address bytes are transferred in highest order to lowest order sequence. Sequential data bytes in SDR are transferred in lowest address to highest address order. Sequential data bytes in DDR are transferred only in byte pairs (words) where the byte order depends on the order in which the bytes are written or programmed in that protocol mode. Sequential data bytes are transferred in lowest address to highest address order. Serial peripheral interface (SPI, 1S-1S-1S) on page 13 through Quad peripheral interface (QPI, 4S-4S-4S and 4S-4D-4D) show all transaction formats by protocol mode.

Address space maps

3 Address space maps

The HL-T/HS-T family supports 24-bit as well as 32-bit (4-Byte) addresses, to enable 256Mb or 512Mb or 1Gb density devices. 4-Byte addresses allow direct addressing of up to 4GB (32Gb) address space. The address byte option can be changed by writing the respective configuration registers OR there are separate transactions also available to enter (EN4BA_0_0) and exit (EX4BA_0_0) the 4-byte address mode.

Besides flash memory array, HL-T/HS-T family includes separate address spaces for Manufacturer ID, Device ID, Unique ID, Serial Flash Discoverable Parameters (SFDP), Secure Silicon Region (SSR), and Registers.

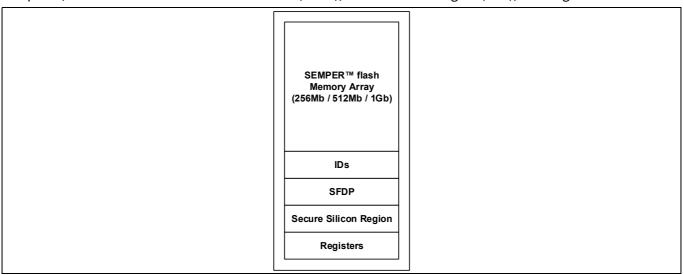

Figure 39 HL-T/HS-T address space map overview

3.1 SEMPER™ Flash memory array

The main flash array is divided into units called physical sectors.

The HL-T/HS-T family sector architecture supports the following options:

- 256Mb, 512Mb, 1Gb supports 256KB Uniform sector options
- 256Mb, 512Mb, 1Gb Hybrid sector options
 - Physical set of thirty-two 4KB sectors and one 128KB sector at the top or bottom of address space with all remaining sectors of 256KB
 - Physical set of sixteen 4KB sectors and one 192KB sector at both the top and bottom of the address space with all remaining sectors of 256KB

The combination of the sector architecture selection bits in Configuration Register-1 and Configuration Register-3 support the different sector architecture options of the HL-T/HS-T family. See **Registers on page 72** for more information.

Quad SPI, 1.8V/3.0V
Address space maps

These are condensed tables that use a couple of sectors as references. There are address ranges that are not explicitly listed. All 4KB sectors have the pattern xxxxx000h-xxxxxFFFh. All 256KB sectors have the pattern xxx00000h-xxxx3FFFFh, xxx40000h-xxx7FFFFh, xx80000h-xxxCFFFFh, or xxD0000h-xxxFFFFFh.

3.2 ID address space

This particular region of the memory is assigned to manufacturer, device, and unique identification:

- The manufacturer identification is assigned by JEDEC (see Table 89).
- The device identification is assigned by CYPRESS™ (see Table 89).
- A 64-bit unique number is located in 8 bytes of the Unique Device ID address space. This Unique ID can be used as a software readable serial number that is unique for each device (see **Table 90**).

There is no address space defined for these IDs as they can be read by providing the respective transactions only. The transactions do not need the address to read these IDs. The data in this address space is read-only data.

3.3 JEDEC JESD216 serial flash discoverable parameters (SFDP) space

The SFDP standard provides a consistent method of describing the functional and feature capabilities of this serial flash device in a standard set of internal parameter tables. These parameter tables can be interrogated by host system software to enable adjustments needed to accommodate divergent features. The SFDP address space has a header starting at address zero that identifies the SFDP data structure and provides a pointer to each parameter. The SFDP address space is programmed by CYPRESS™ and read-only for the host system (see Table 85 through Table 88).

Table 6 SFDP overview address map

Byte address	Description
0000h	Location zero within JEDEC JESD216D SFDP space - start of SFDP header
""	Remainder of SFDP header followed by undefined space
0100h	Start of SFDP parameter tables The SFDP parameter table data starting at 0100h
	Remainder of SFDP parameter tables followed by either more parameters or undefined space

3.4 SSR address space

Each HS/L-T family memory device has a 1024-byte Secure Silicon Region which is OTP address space. This address space is separate from the main flash array. The SSR area is divided into 32 individually lockable, 32-byte aligned and length regions.

In the 32-byte region starting at address zero:

- The 16 lowest bytes contain a 128-bit random number. The random number cannot be written to, erased or programmed and any attempts will return an PRGERR flag.
- The next four bytes are used to provide one bit per secure region (32 bits in total) to permanently protect once set to "0" from writing, erasing or programming.
- · All other bytes are reserved.

The remaining regions are erased when shipped from CYPRESS™, and are available for programming of additional permanent data.

Quad SPI, 1.8V/3.0V Address space maps

Table 7 SSR address map

Region	Byte address range	Contents	Initial delivery state
	000h	LSB of CYPRESS™ Programmed Random Number	
			CYPRESS™ Programmed Random Number
	00Fh	MSB of CYPRESS™ Programmed Random Number	
Region 0	010h to 013h	Region Locking Bits Byte 10h [bit 0] locks region 0 from programming when = 0 Byte 13h [bit 7] locks region 31 from programming when = 0	All Bytes = FFh
	014h to 01Fh	Reserved for future use (RFU)	All Bytes = FFh
Region 1	020h to 03Fh	Available for User Programming	All Bytes = FFh
Region 2	040h to 05Fh	Available for User Programming	All Bytes = FFh
		Available for User Programming	All Bytes = FFh
Region 31	3E0h to 3FFh	Available for User Programming	All Bytes = FFh

Registers 3.5

Registers are small groups of memory cells used to configure how the HS/L-T family memory device operates, or to report the status of device operations. The registers are accessed by specific commands and addresses. Table 8 shows the address map for every available register in this flash memory device.

Features

4 Features

4.1 Error detection and correction

HL-T/HS-T family devices support error detection and correction by generating an embedded Hamming error correction code during memory array programming. This ECC code is then used for error detection and correction during read operations. The ECC is based on a 16-byte data unit. When the 16-byte data unit is loaded into the Program Buffer and is transferred to the 128-bits flash memory array Line for programming (after an erase), an 8-bit ECC for each data unit is also programmed into a portion of the memory array that is not visible to the host system software. This ECC information is then checked during each flash array read operation. Any 1-bit error within the data unit will be corrected by the ECC logic. The 16-byte data unit is the smallest program granularity on which ECC is enabled.

When any amount of data is first programmed within a 16-byte data unit, the ECC value is set for the entire data unit. If additional data is subsequently programmed into the same data unit, without an erase, then the ECC for that data unit is disabled and the 1-bit ECC disable bit is set. A sector erase is needed to again enable ECC on that data unit.

These are automatic operations transparent to the user. The transparency of the ECC feature enhances data reliability for typical programming operations which write data once to each data unit while also facilitating software compatibility with previous generations of products by still allowing for single-byte programming and bit-walking (in this case, ECC will be disabled) in which the same data unit is programmed more than once.

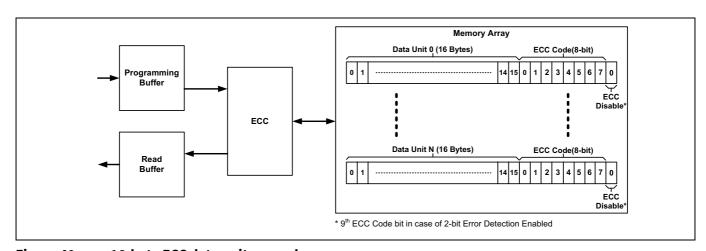

Figure 40 16-byte ECC data unit example

SEMPER[™] NOR Flash supports 2-bit error detection as the default ECC configuration. In this configuration, any 1-bit error in a data unit is corrected and any 2-bit error is detected and reported. The 16-byte unit data requires a 9-bit Error Correction Code for 2-bit error detection. When 2-bit error detection is enabled, byte-programming, bit-walking, or multiple program operations to the same data unit (without an erase) are not allowed and will result in a Program Error. Changing the ECC mode from 1-bit error detection to 2-bit error detection, or from 2-bit error detection to 1-bit error detection will invalidate all data in the memory array. When changing the ECC mode, the host must first erase all sectors in the device. If the ECC mode is changed without erasing programmed data, subsequent read operations will result in undefined behavior.

256Mb/512Mb/1Gb SEMPER™ Flash Quad SPI, 1.8V/3.0V

Features

4.1.1 ECC error reporting

There are four methods for reporting to the host system when ECC errors are detected.

- ECC Data Unit Status provides the status of 1-bit or 2-bit errors in data units.
- ECC Status Register provides the status of 1-bit or 2-bit errors since the last ECC clear or reset.
- The Address Trap Register captures the address location of the first ECC error encountered after POR or reset during memory array read.
- An ECC Error Detection counter keeps a tally of the number of 1-bit or 2-bit errors that have occurred in data units during reads.

4.1.1.1 ECC data unit status (EDUS)

- The status of ECC in each data unit is provided by the 8-bit ECC Data Unit Status.
- The ECC status transaction outputs the ECC status of the addressed data unit. The contents of the ECC Data Unit status then indicate, for the selected data unit, whether there is a 1-bit error corrected, 2-bit error detected, or the ECC is disabled for that data unit.

Table 9 ECC data unit status

idates	E G G G G G G G G G G G G G G G G G G G					
Bits	Field name	Function	Read/Write N = Nonvolatile V = Volatile	Factory default (binary)	Description	
EDUS[7:4]	RESRVD	Reserved For future use	V => R	0000	These bits are Reserved for future use.	
EDUS[3]	ECC2BD	ECC Error 2-bit Error Detection Flag	V => R	0	This bit indicates whether a two bit error is detected in the data unit, if two bit ECC error detection is enabled CFR4V[3] = 1. When CFR4V[3] = 0 and 2-bit error detection is disabled, ECC2BD bit will always be '0'. Note If 2 bit error detection is enabled (CFR4V[3] = 1), the ECCOFF bit will not be set to 1b while performing single byte programming or bit walking in a data unit that was already partially programmed. An attempt to do such byte programming or bit walking will result in a Program Error. Selection Options: 1 = Two Bit Error detected	
		Reserved For future			0 = No error	
EDUS[2]	RESRVD	use	V => R	0	This bit is Reserved for future use.	
EDUS[1]	ECC1BC	ECC Error 1-bit Error Detection and Correction Flag	V => R	0	This bit indicates whether an error was corrected in the data unit. Selection Options: 1 = Single Bit Error corrected in the addressed data unit 0 = No single bit error was corrected in the addressed data unit	
EDUS[0]	ECCOFF	Data Unit ECC OFF/ON Flag	V => R	0	This bit indicates whether the ECC syndrome is OFF in the data unit. Selection Options: 1 = ECC is OFF in the selected data unit 0 = ECC is ON in the selected data unit Dependency: CFR4x[3]	

256Mb/512Mb/1Gb SEMPER™ Flash Quad SPI, 1.8V/3.0V

Features

4.1.1.2 ECC status register (ECSV)

- An 8-bit ECC Status Register provides the status of 1-bit or 2-bit errors during normal reads since last ECC clear or reset. ECC Status Register does not have user programmable nonvolatile bits, all defined bits are volatile read only bits. The default state of these bits are set by hardware.
- ECC Status Register can be accessed through the Read Any Register transaction. The correct sequence for Read Any Register based ECSV is read as follows:
 - Read data from memory array using any of the Read transaction
 - ECSV is updated by the device
 - Read Any Register transaction of ECSV provides the status of any ECC event since the last clear or reset.
- ECSV is cleared by POR, CS# Signaling Reset, Hardware/Software reset, or a Clear ECC Status Register transaction.

4.1.1.3 ECC error address trap (EATV)

• A 32-bit register is provided to capture the ECC data unit address where an ECC error is first encountered during a read of the flash array. Only the address of the first enabled error type ("2-bit only" or "1-bit or 2-bit" as selected in CFR4N[3]) encountered after POR, hardware reset, or the ECC Clear transaction is captured. The EATV Register is only updated during Read transactions.

The EATV Register contains the address that was accessed when the error was detected. The failing bits may not be located at the exact address indicated in the register, but will be located within the aligned 16-byte ECC data unit where the error was detected. If errors are found in multiple ECC data units during a single read operation, only the address of the first failing ECC unit address is captured in the EATV Register.

When 2-bit error detection is not enabled and the same ECC unit is programmed more than once, ECC error detection for that ECC unit is disabled, therefore no error can be recognized to trap the address.

The Address Trap Register has a valid address when the ECC Status Register (ECSV) bit 3 or 4 = 1.

- The Address Trap Register can be read using the Read Any Register transaction.
- Clear ECC Status Register transaction, POR, or CS# Signaling/Hardware/Software reset clears the Address Trap Register.

4.1.1.4 ECC error detection counter (ECTV)

 A 16-bit register is provided to count the number of 1-bit or 2-bit errors that occur as data is read from the flash memory array. Only errors recognized in the main array will cause the Error Detection Counter to increment. ECTV Register is only updated during Read transaction. Read ECC Status transaction does not affect the ECTV Register.

The 16-bit Error Detection Counter will not increment beyond FFFFh. However, the ECC continues to work.

Note that during continuous read operations, when a 1-bit or a 2-bit error is detected, the clock may continue toggling and the memory device will continue incrementing the data address and placing new data on the DQ signals; any additional data units with errors that are encountered will be counted until CS# is brought back HIGH.

During a read transaction only one error is counted for each data unit found with an error. Each read transaction will cause a new read of the target data unit. If multiple read transactions access the same data unit containing an error, the error counter will increment each time that data unit is read.

When 2-bit error detection is not enabled and the same data unit is programmed more than once, ECC error detection for that data unit is disabled so, no error can be recognized or counted.

- The ECC Error Detection Counter Register can be read using the Read Any Register transaction.
- ECTV Register is set to 0 on POR, CS# Signaling/Hardware/Software Reset or with Clear ECC Status Register transaction.

Quad SPI, 1.8V/3.0V

Features

4.1.2 ECC related registers and transactions

4.2 Infineon® Endurance Flex architecture (wear leveling)

Infineon[®] Endurance Flex architecture allows partitioning of the main memory array into regions which can be configured as either high endurance or long retention. Infineon[®] Endurance Flex architecture implements wear leveling in high endurance regions where program/erase cycles are spread evenly across all the sectors which are part of the wear leveling pool. This greatly improves the reliability of the device by avoiding premature wear-out of an individual sector.

Architecturally, Infineon[®] Endurance Flex architecture's wear leveling algorithm is based on a mapping of logical sectors to physical sectors. During the lifetime of the part, this mapping is changed to maintain a uniform distribution of program/erase cycles over all physical sectors. The logical to physical mapping information is stored in a dedicated flash array which is updated when sectors are swapped. Sector swaps occur when an erase transaction is given.

Infineon[®] Endurance Flex architecture's high endurance region requires a minimum set of 20 sectors. To provide flexibility between configuring long retention, high endurance, or both regions, a four pointer architecture is provided. The factory default setting designates all sectors as high endurance as part of the wear leveling pool with all pointers disabled. The four pointers can be used to form a maximum of five regions which can each be configured as long retention or high endurance.

Figure 41 provides an overview of the Infineon[®] Endurance Flex architecture. It shows the five possible regions based on different sector architecture.

Note

12.4KB sectors are not part of the Infineon® Endurance Flex architecture.

Quad SPI, 1.8V/3.0V

Features

Features

Table 11 Region definitions^[13, 14, 15, 16]

Region	Lower limit	Upper limit
0	Sector 0	Address Pointer 1
1	Address Pointer 1	Address Pointer 2
2	Address Pointer 2	Address Pointer 3
3	Address Pointer 3	Address Pointer 4
4	Address Pointer 4	Highest Sector

Notes

Pointer#4 address > Pointer#3 address

Pointer#3 address > Pointer#2 address

Pointer#2 address > Pointer#1 address

14.4KB sectors are excluded.

4.2.1 Configuration 1: Maximum endurance - Single high endurance region

Maximum endurance is achieved when all 256KB sectors are designated as high endurance. All sectors must be designated as high endurance using the Infineon[®] Endurance Flex architecture pointer. Maximum endurance pointer configuration is shown in **Table 12**.

Table 12 Infineon® Endurance Flex architecture pointer values for maximum endurance configuration^[17]

	1	I	1		1	
Pointer #	Pointer address EPTADn[8:0]	Region type ERGNTn	Pointer enable# EPTEBn	Global region selection GBLSEL	Wear leveling enable WRLVEN	
0	N/A	N/A	N/A	1'b1	1'b1	
1	9'b11111111					
2	9'b11111111	1'b1	11/61	1'b1	N1/A	NI/A
3	9'b11111111		1 01	N/A	N/A	
4	9'b11111111					

Note

4.2.2 Configuration 2: Two region selection - One long retention region and one high endurance region

Sectors for long retention or high endurance must be delineated using the Infineon[®] Endurance Flex architecture pointer. Region 0 is defined as long retention and consists of 16 sectors. Region 1 is defined as high endurance and has 240 sectors. The pointer setup for two region configuration is shown in **Table 13**. The number of pointers defined is based on the number of regions configured.

Table 13 Infineon® Endurance Flex architecture pointer values for two region configuration

Pointer #	Pointer address EPTADn[8:0]	Region type ERGNTn	Pointer enable# EPTEBn	Global region selection GBLSEL	Wear leveling enable WRLVEN
0	N/A	N/A	N/A	1'b0	1'b1
1	9'b000010000	1'b1	1'b0		
2				NI/A	NI/A
3	9'b11111111	1'b1	1'b1	N/A	N/A
4					

^{13.} The pointer addresses must obey the following rules:

^{15.} It is required that the high data endurance and long data retention regions are configured at the time the device is first powered-up by the customer. Once configured, they can never be changed again.

^{16.} The minimum size of any high endurance region is 20 sectors.

^{17.} This is also the default configuration of the device.

Quad SPI, 1.8V/3.0V

4.3 Data integrity CRC

HL-T/HS-T family devices have a group of transactions to perform a hardware accelerated Cyclic Redundancy Check (CRC) calculation over a user defined address range in the memory array. The calculation is another type of embedded operation similar to programming or erase, in which the device is busy while the calculation is in progress. The CRC operation uses the following CRC32 polynomial to determine the CRC check-value.

$$\mathsf{CRC32\ Polynomial:}\ X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^{9} + X^{8} + X^{6} + 1$$

The check-value generation sequence is started by entering the DICHK_4_1 transaction. The transaction includes loading the beginning address into the CRC Start Address Register identifying the beginning of the address range that will be covered by the CRC calculation. The transaction also includes loading the ending address into the CRC End Address Register. Bringing CS# HIGH starts the CRC calculation. The CRC process calculates the check-value on the data contained at the starting address through the ending address.

During the calculation period the device goes into the Busy state (STR1V[0] - RDYBSY = 1). Once the check-value calculation has completed the device returns to the Ready state (STR1V[0] - RDYBSY = 0) and the calculated check-value is available to be read. The check-value is stored in the Data Integrity CRC Register (DCRV[31:0]) and can be read using Read Any Register (RDARG_C_0) transaction.

The check-value calculation can only be initiated when the device is in Standby State; and once started it can be suspended with the CRC Suspend transaction (SPEPD_0_0) to read data from the memory array. During the Suspended state the CRC Suspend Status Bit in the Status Register 2 will be set (STR2V[4] - DICRCS = 1). Once suspended, the host can read the Status Register, read data from the array and can resume the CRC calculation by using the CRC Resume transaction (RSEPD_0_0).

The Ending Address (ENDADD) must be at least two addresses higher than the Starting Address (STRADD). If ENDADD < STRADD + 3 the check-value calculation will abort and the device will return to the Ready state (STR1V[0] - RDYBSY = 0). Data Integrity CRC abort status bit will be set (STR2V[3] - DICRCA = 1) to indicate the aborted condition. The DICRCA bit can be cleared, once set, by Software reset or a valid subsequent CRC command execution. If ENDADD < STRADD + 3, the check-value will hold indeterminate data.

Note Any invalid transaction during CRC check-value calculation can corrupt the check-value data.

4.3.1 Data integrity check related registers and transactions

Features

4.4 Data protection schemes

Data protection is required to safeguard against unintended changes to stored data and device configuration. This includes inadvertent erasing or programming the memory array as well as writing to the configuration registers which can alter the functionality of the device. Three types of protection schemes are discussed which range from protecting either a single or a group of sectors to either a portion or the complete memory array.

Figure 43 shows an overview of different protection schemes along with applicable data regions.

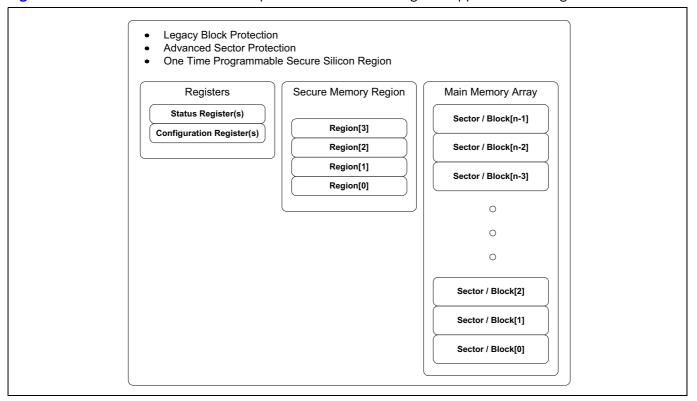

Figure 43 Data protection and security (write/program/erase) schemes

4.4.1 Legacy block protection (LBP)

The Legacy Block Protection (LBP) is a block-based data protection scheme. LBP supports compatibility with legacy serial NOR Flash devices. LBP provides protection for data in the memory array and device configuration by protecting Status and Configuration registers.

4.4.1.1 Memory array protection

The protection for the memory array is with block size selection, which is achieved through a combination of bits present in the Status Register 1 (STR1N[4:2]/STR1V[4:2] - LBPROT[2:0]) and Configuration Register 1 (CFR1N[5]/CFR1V[5] - TBPROT).

Quad SPI, 1.8V/3.0V

Features

Table 16 provides the LBP memory array block selection summary.

Table 16 Legacy block memory array protection selection

CFR1N[5]/CFR1V[5] TBPROT	STR1N[4]/STR1V[4] LBPROT[2]	STR1N[3]/STR1V[3] LBPROT[1]	STR1N[2]/STR1V[2] LBPROT[0]	Memory array block size	256Mb (KBs)	512Mb (KBs)	1Gb (KBs)
0	0	0	0	None	0	0	0
0	0	0	1	Upper 64th	512	1024	2048
0	0	1	0	Upper 32nd	1024	2048	4096
0	0	1	1	Upper 16th	2048	4096	8192
0	1	0	0	Upper 8th	4096	8192	16384
0	1	0	1	Upper 4th	8192	16384	32768
0	1	1	0	Upper Half	16384	32768	65536
0	1	1	1	All sectors	32768	65536	131072
1	0	0	0	None	0	0	0
1	0	0	1	Lower 64th	512	1024	2048
1	0	1	0	Lower 32nd	1024	2048	4096
1	0	1	1	Lower 16th	2048	4096	8192
1	1	0	0	Lower 8th	4096	8192	16384
1	1	0	1	Lower 4th	8192	16384	32768
1	1	1	0	Lower Half	16384	32768	65536
1	1	1	1	All sectors	32768	65536	131072

4.4.1.2 Configuration protection

LBP has selection bits in Configuration Register 1 (CFR1N[4,0]/CFR1V[4,0] - PLPROT, TLPROT) which either permanently or temporarily protect Status and Configuration registers, thereby again protecting the device's configuration. The temporary protection remains in effect until the next power down or hardware reset or CS# signaling reset.

Table 17 Option 2 - Legacy block configuration protection selection^[18]

CFR1N[4]/CFR1V[4] PLPROT	CFR1N[0]/CFR1V[0] TLPROT	Register protection status		
0	0	Status and Configuration registers are unprotected		
1	Х	Status and Configuration registers are permanently protected (TBPROT, LBPROT[2:0], SP4KBS, TB4KBS)		
0	1	Status and Configuration registers are Protected till next Power down (TBPROT, LBPROT[2:0], SP4KBS, TB4KBS)		

Note

4.4.1.3 Write protect signal

The Write Protect (DQ2_WP#) input in combination with the Status Register Write Disable bit (STR1x[7]) provide hardware input signal controlled protection. When WP# is LOW and STR1x[7] is set to "1" Status Register 1 (STR1N and STR1V) and Configuration register-1 (CFR1N and CFR1V) are protected from alteration. This prevents disabling or changing the protection defined by the Block Protect bits.

^{18.} Protecting the configuration also protects the memory array blocks which have been selected for protection.

4.4.1.4 Legacy block protection flowchart

The LBP protection scheme flowchart is shown in Figure 44.

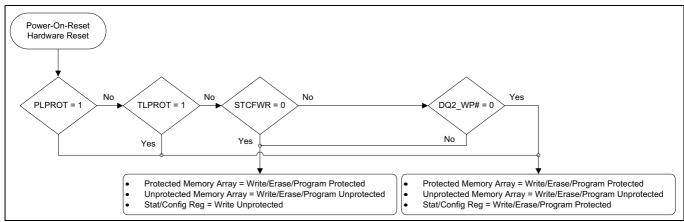

Figure 44 Legacy block protection flowchart

4.4.1.5 LBP related registers and transactions

	Write Enable (WRENB_0_0)	Write Enable (WRENB_0_0)	

4.4.2 Advanced sector protection (ASP)

The Advanced Sector Protection (ASP) scheme allows each memory array sector to be independently controlled for protection against erasing or programming, either by volatile or nonvolatile locking features. The nonvolatile locking configuration can also be locked, as well as password-protected.

The main memory array sectors are protected against erase and program by volatile (DYB) and nonvolatile (PPB) protection bit pairs. Each DYB/PPB bit pair can be individually set to '0' protecting the related sector or cleared to '1' un-protecting the related sector. DYB protection bits can be set and cleared as often as needed whereas PPB bits being nonvolatile must adhere to their respective technology based endurance requirements. Figure 45 shows an overview of ASP.

Figure 45 **Advanced sector protection (Nonvolatile)**

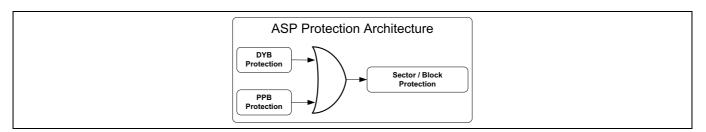

Figure 46 **DYB and PPB protection control**

ASP provides a rich set of configuration options producing multiple data protection schemes which can be employed based on design or system needs. These configuration options are discussed in **Configuration** protection on page 39 through ASP related registers and transactions on page 44.

4.4.2.1 Configuration protection

ASP provides provisions to protect device's configuration through Persistent Protection scheme. Selecting bit 1 in Advanced Sector Protection Register (ASPO[1] - ASPPER) selects the Persistent Protection scheme and protects the following registers or register bits from write or program:

- CFR1V[6,5,4,2]/CFR1N[6,5,4,2] SP4KBS, TBPROT, PLPROT, TB4KBS
- CFR3N[3]/CFR3V[3] UNHYSA
- ASPO[15:0]
- PWDO[63:0]

The persistent protection scheme flowchart is shown in Figure 47.

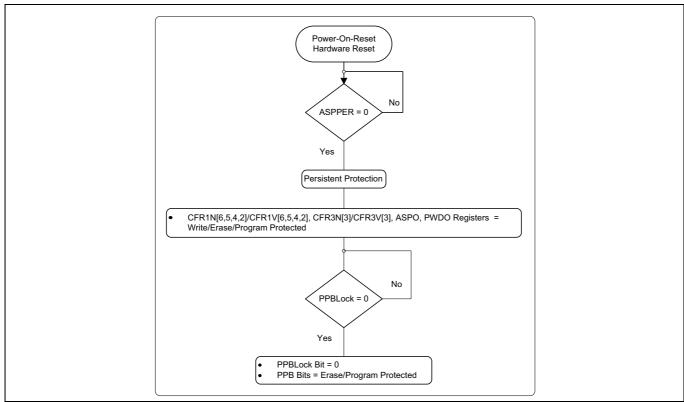

Figure 47 Persistent protection scheme flowchart

4.4.2.2 Dynamic DYB (volatile) sector protection

Dynamic Protection Bits (DYB) are volatile and unique for each sector and can be individually modified. DYBs only control protection for sectors that have their PPBs cleared. By issuing the DYB Write transaction, the DYB are set to 0 or cleared to 1, thus placing each sector in the protected or unprotected state respectively. This feature allows software to easily protect sectors against inadvertent changes, yet does not prevent the easy removal of protection when changes are needed. The DYB can be set to 0 or cleared to 1 as often as needed

In Dynamic Sector Protection scheme, an option is provided to reset all DYB volatile protection bits to '0' upon power up (protected), essentially protecting all sectors from erase or program. Selecting bit 4 in the Advanced Sector Protection Register (ASPO[4] - ASPDYB) selects the Dynamic Protection (DYB) for all sectors at power-up protection scheme. These DYB bits can be individually set to '1', if desired. The Dynamic Sector Protection scheme flowchart showing power up protection is shown in **Figure 48**.

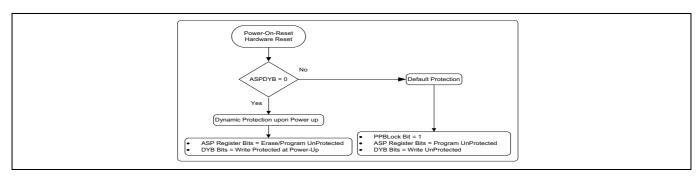

Figure 48 Dynamic sector protection scheme flowchart

4.4.2.3 Permanent/Temporary PPB (nonvolatile) sector protection

Each nonvolatile bit (PPB) provides nonvolatile protection for an individual memory sector, which remains locked (protection enabled) until its corresponding bit is cleared to 1. There are two options to control the PPB based nonvolatile selection in ASP, namely Permanent and Temporary.

4.4.2.4 Permanent PPB protection scheme

The PPB are located in a separate nonvolatile flash array. One of the PPB bits is assigned to each sector. When a PPB is programmed to 0 its related sector is protected from program and erase operations. The PPB are programmed individually but must be erased as a group, similar to the way individual words may be programmed in the main array but an entire PPB sector must be erased at the same time. Programming a PPB bit requires the typical word programming time. During a PPB bit programming operation or PPB bit erasing, the Status Register can be accessed to determine when the operation has completed. Erasing all the PPBs requires typical sector erase time.

Permanent PPB based protection scheme, as the name applies, is permanent and can never be altered. Once the PPB architecture is decided, selecting bit 0 in Advanced Sector Protection Register (ASPO[0]) enables the Permanent Protection for all PPB bits essentially disabling all PPB erase and program operations. ASPO is also protected from write or program.

The Permanent PPB Protection scheme flowchart is shown in Figure 49.

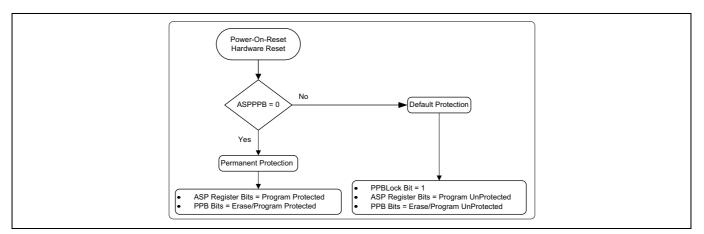

Figure 49 Permanent PPB sector protection flowchart

4.4.2.5 Temporary PPB protection scheme

PPB based nonvolatile protection architecture can be temporarily locked where erasing and programming of the individual PPB bits is inhibited. The Persistent Protection Lock Bit (PPBLock) is a volatile bit for protecting all PPB bits. When cleared to 0, it locks all PPBs and when set to 1, it allows the PPBs to be changed. There is only one PPB Lock Bit per device. The PPBLock transaction (WRPLB_0_0) is used to clear the bit to 0. The PPB Lock Bit must be cleared to 0 only after all the PPBs are configured to the desired settings. The PPB Lock Bit is set to 1 during POR or a Hardware Reset. When cleared with the PPBLock transaction, no software command sequence can set PPBLock, only another Hardware Reset or Power-Up can set PPBLock.

Note Temporary PPB Protection does not require any ASP configuration.

4.4.2.6 Password protection scheme

Password Protection scheme allows an even higher level of security, by requiring a 64-bit password for setting PPBLock. In addition to this password requirement, after Power-Up or Hardware Reset, the PPB Lock Bit is cleared to 0 to ensure protection at Power-Up. Successful execution of the Password Unlock transaction by entering the entire password sets the PPB Lock Bit to 1, allowing for sector PPB modifications. Selecting bit 2 in Advanced Sector Protection Register (ASPO[2] - ASPPWD) selects the Password Protection scheme. Password Protection scheme also protects ASPO from write or program.

Note A password must be programmed before selecting the password protection scheme. The password unlock SPI transaction (PWDUL_0_1) is used to provide a password for comparison.

The Password Protection scheme flowchart is shown in Figure 50.

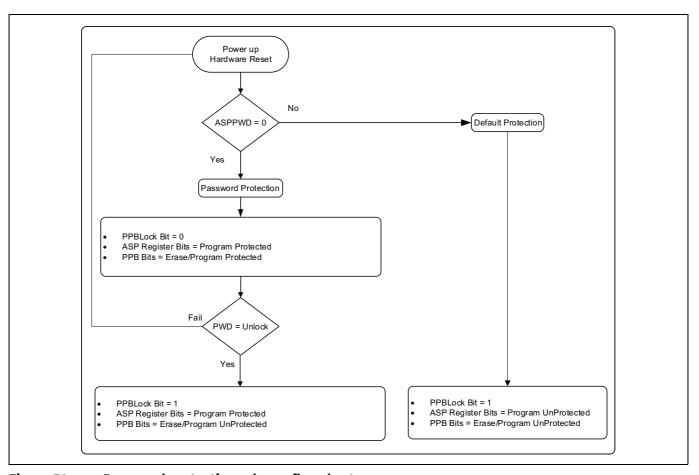

Figure 50 Password protection scheme flowchart

4.4.2.7 Read password protection scheme

The Read Password Protection scheme replaces the Password Protection scheme and provides the most data protection. The Read Password Protection scheme enables protecting the flash Memory Array from read, program, and erase. Only the lowest or highest (256KB) sector address range, selected by bit 5 of Configuration Register 1 (CFR1x[5] - TBPROT), remains readable until a successful Password Unlock transaction is complete. A '0' selects from the top most sector and a '1' selects from the bottom most sector irrespective of the sector address supplied in the read transaction. Note that reads from the read-protected portion of the array will alias back to the readable sector.

Clear Program and Erase Failure Flags transaction, all memory array Read transactions, Password Unlock transaction, Read manufacturer and device ID transaction, Read SFDP transaction, Read Status Register -1 transaction, Read Status Register-2 transaction, Read ECC Status transaction, Clear ECC Status Register transaction, and Enter DPD Mode transaction are allowed during Password Read Mode before the Password is supplied.

Note A password must be programmed before selecting the Read Password Protection Scheme. The password unlock SPI transaction

(PWDUL_0_1) is used to provide a password for comparison.

The Read Password Protection scheme flowchart is shown in Figure 51.

Quad SPI, 1.8V/3.0V

Features

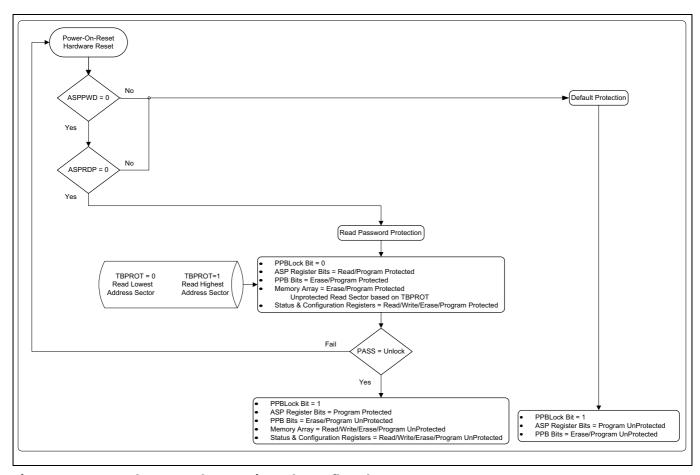

Figure 51 Read password protection scheme flowchart

4.4.2.8 PPB Bits - OTP selection

ASP provides a configuration option to permanently disable the PPB erase transaction (ERPPB_0_0). This makes all PPB bits OTP. With this option, once the PPB protection is selected, it can never be changed. Selecting bit 3 in Advanced Sector Protection Register (ASPO[3] - ASPPPB) makes PPB bits OTP.

4.4.2.9 General ASP guidelines

- Persistent protection (ASPPER) and Password protection (ASPPWD) are mutually exclusive only one option can be programmed.
- Read Password protection (ASPRDP) if desired, must be programmed at the same time as Password protection (ASPPWD).
- Once the password is programmed and verified, the Password Protection scheme (ASPPWD) must be programmed (to 0) to prevent reading the password.
- When the Read Password scheme and Password Protection scheme are enabled (i.e. ASPO[5] ASPRDP, ASPO[2] ASPPWD are programmed to 0), then all addresses are redirected to the Boot Sector until the password unlocking sequence is properly entered with the correct password. At which time, the Read Password Mode is disabled and all addressing will select the proper location.
- Programming memory spaces or writing registers is not allowed when Read Password Protection Mode is active.

4.4.2.10 ASP related registers and transactions

4.4.3 Secure silicon region (SSR)

Secure Silicon Region (SSR) is a 1024 byte memory region (separate from the main memory array). The 1024 bytes are divided into 32, individually lockable 32-byte regions. **Figure 52** provides an overview of SSR.

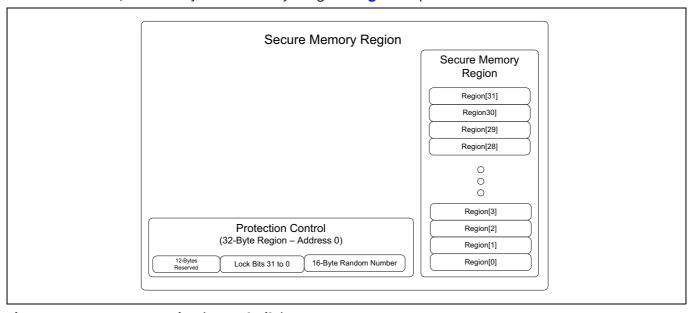

Figure 52 OTP protection (nonvolatile)

The first 32-byte region (starting at address 0) provides the protection mechanism for the other 32-byte regions. The sixteen lowest bytes of this region contain a 128-bit random number. The random number cannot be written to, erased or programmed. The next four bytes (32 bits in total) of this region provide protection from programming if set to '0' for the remaining 32-byte regions - one bit per 32-byte region. All other bytes are reserved.

Note Attempting to Erase or Program the 128-bit random number will result in ERSERR or PRGERR, respectively. A hardware Reset is required to bring the device back to Standby mode.

4.5 SafeBoot

SEMPER™ Flash memory devices contain an embedded microcontroller which is used to initialized the device, manage embedded operations, and perform other advanced functionality. An initialization failure of this embedded microcontroller or corruption of the nonvolatile configuration registers can render the flash device unusable. Baring a catastrophic event, such as permanent corruption of the embedded microcontroller firmware, it is possible to recover the device.

The SafeBoot feature allows Status Register polling to detect an embedded microcontroller initialization failure or configuration register corruption through error signatures.

4.5.1 Microcontroller initialization failure detection

If the microcontroller embedded in the flash device fails to initialize, a hardware reset can recover the device, unless it is a catastrophic failure. This hardware reset must be initiated by the Host controller. Upon detecting a failed microcontroller initialization, the flash device automatically reverts to its Default Boot mode (1S-1S-1S) and provides a failure signature in its Status Register.

Table 21 shows the device's Status Register bits upon detecting an initialization failure.

Table 21 Status register 1 power-on detection signature

Bit	Field name	Function	Detection signature
STR1V[7]	STCFWR	Status Register and Configuration Registers Protection Selection against write (erase/program)	0
STR1V[6]	PRGERR	Programming Error Status Flag	1
STR1V[5]	ERSERR	Erasing Error Status Flag	1
STR1V[4]		Legacy Block Protection based memory Array size selection	0
STR1V[3]	LBPROT[2:0]	Note: LBPROT[2:0] can be anything from 000 to 111 based on Block Protection configu-	0
STR1V[2]		ration.	0
STR1V[1]	WRPGEN	Write/Program Enable Status Flag	0
STR1V[0]	RDYBSY	Device Ready/Busy Status Flag	1

Table 22 Interface configuration upon detecting power-on failure^[19]

Interface	Transactions supported	Register type	Address (# of bytes)	Frequency of operation	Register read latency (# of clock cycles)	Output impedance
SPI (1S-1S-1S)	Read Status Register 1 (RDSR1_0_0) Read Any Register (RDARG_C_0)	Status Register (Volatile Only)	4	Maximum (allowed for RDSR1_0_0, RDARG_C_0)	2	45Ω

Note

^{19.} For reading the Status Register, providing the NonVolatile Status Register address to RDARG_C_0 will produce indeterminate results.

4.5.1.1 Host polling behavior

The host will need to go through a Status Register polling sequence to determine if an initialization failure has occurred in the device. The flowchart for the sequence is shown in **Figure 53**.

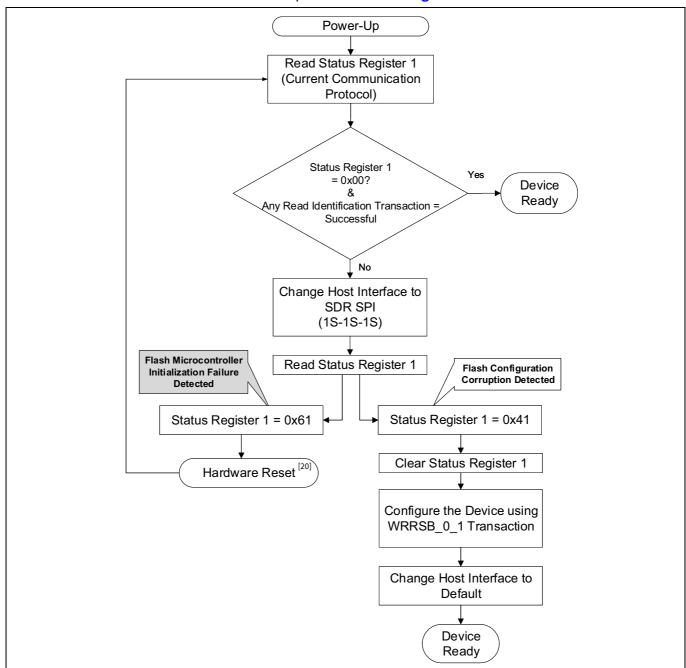

Figure 53 Host polling sequence for microcontroller initialization failure detection

Note The polling sequence must start from the higher I/O interface configuration to lower I/O interface configuration only. For example, 4S-4D-4D to 1S-1S-1S.

20. If you have Vcc within specifications and a hardware reset does not resolve the issue, replace the flash device.

Quad SPI, 1.8V/3.0V

Features

4.5.1.2 Microcontroller initialization failure detection related registers and transactions

Table 23 Microcontroller initialization failure related registers and transactions

Related registers	Related SPI transactions (see Table 73 on page 91)	Related quad SPI transactions (see Table 77 on page 98)	
Status Register 1 Volatile (STR1V)	Read Any Register (RDARG_C_0)	N/A	
(see Table 41 on page 73)	Read Status Register -1 (RDSR1_0_0)	N/A	

4.5.2 Configuration corruption detection

If during device's configuration update, such as writing to a nonvolatile register, a power loss occurs or a hardware reset is initiated, the write register transaction will get interrupted. The device will return to Standby mode, but the nonvolatile register data is most likely corrupted since the embedded write operation was prematurely terminated. During the next power-up, the configuration corruption is detected and the device reverts to its Default Boot mode (1S-1S-1S) and allows rewriting the configuration again. The device will maintain the configured protection scheme.

Table 24 shows the device's Status Register bits upon detecting a configuration corruption.

Table 24 Status Register 1 configuration corruption detection signature

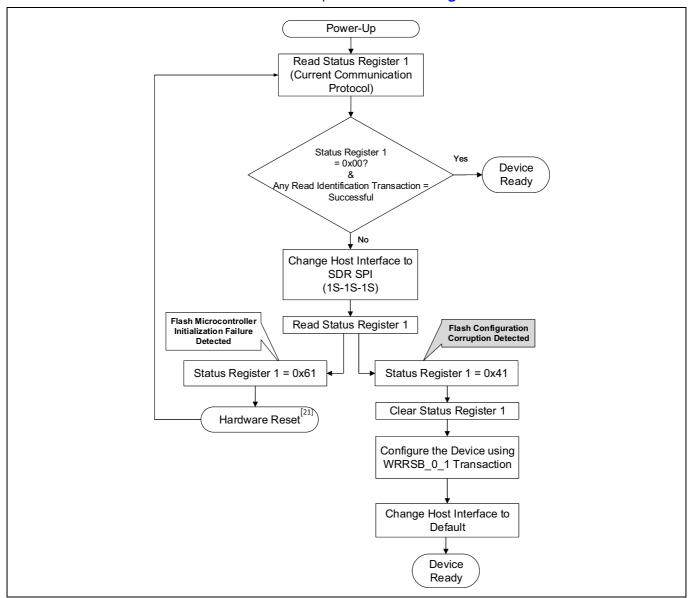

Bit	Field name	Function	Detection signature
STR1V[7]	STCFWR	Status Register and Configuration Registers Protection Selection against write (erase/program)	0
STR1V[6]	PRGERR	Programming Error Status Flag	1
STR1V[5]	ERSERR	Erasing Error Status Flag	0
STR1V[4]	LBPROT[2:0]	Legacy Block Protection based memory Array size selection	0

Table 25 Interface configuration upon detecting configuration corruption

Interface	Transactions supported	Address (# of bytes)	Frequency of operation	Register read latency (# of clock cycles)	Output impedance
SPI (1S-1S-1S)	All SPI (1S-1S-1S) Trans- actions	4	Maximum	2	45Ω

Host polling behavior 4.5.2.1

The host will need to go through a Status Register polling sequence to determine if a Configuration corruption has occurred in the device. The flowchart for the sequence is shown in Figure 54.

Host polling sequence for configuration corruption detection Figure 54

Note The polling sequence must start from a higher I/O interface configuration to a lower I/O interface configuration. ration. As an example, 4S-4D-4D to 1S-1S-1S. Not the other way around.

^{21.} If you have Vcc within specifications and a hardware reset does not resolve the issue, replace the flash device.

Features

4.5.2.2 Configuration corruption detection related registers

Status Register 1 Volatile (STR1V) (see Table 41 on page 73)	All 1S-1S-1S Transactions	N/A	

4.6 AutoBoot

AutoBoot allows the host to read data from HL-T/HS-T family of devices after power up or after a hardware reset without having to send any read transactions (including the address). Based on the device configuration, data is output on the interface I/Os once CS# is brought LOW and CK is toggled.

The starting address for the read data is specified in the AutoBoot Register (ATBN[31:9] - STADR[22:0]). This starting address can be at any page boundary location in the memory (512 byte page boundary). Also identified in the AutoBoot Register is a starting delay which is represented as the number of clock cycles (ATBN[8:1] - STDLY[7:0]). This delay is instituted before the data is read out. The delay can be programmed to meet the host's requirements but a minimum amount is required to meet the memory access times based on the frequency for operation. It is highly recommended to check the Status Register 1 value after successful or unsuccessful AutoBoot execution to verify the configuration corruption (SafeBoot).

Note Wrap function must be disabled for AutoBoot.

Note AutoBoot is disabled when the Read Password feature is enabled, as part of the Advanced Sector Protection. It is recommended to disable AutoBoot (ATBN[0] - ATBTEN) when Read Password feature is enabled.

Note It is highly recommended to assign first AutoBoot address in the Long Retention region.

4.6.1 AutoBoot related registers and transactions

4.7 Read

HL-T/HS-T supports different read transactions to access different memory maps, namely: Read Memory array, Read Device Identification, Read Register, Read Secure Silicon, Read Protection DYB and PPB bits.

These read transactions can use any protocol mentioned in the Transaction Protocols section and potentially can use the following features:

- The read transactions require latency cycles following the address to allow time to access the memory array (except RDAY1_4_0 and RDAY1_C_0 of 1S-1S-1S protocol) (see **Table 49**).
- The read transactions can use the Data Learning Pattern (DLP) driven by the memory, on all data outputs, in the latency cycles immediately before the start of data (see **Data learning pattern (DLP) on page 54**).
- The read transaction has the option of wrapped read length and alignment groups of 8-, 16-, 32-, or 64-bytes (see **Table 52** and **Table 53**).

Features

4.7.1 Read identification transactions

There are three unique identification transactions, each support Single and Quad SPI Protocols (see **Transaction table on page 91**).

4.7.1.1 Read device identification transaction

The Read Device Identification (RDIDN_0_0) transaction provides read access to manufacturer identification and device identification. The transaction uses latency cycles set by (CFR3V[7:6]) to enable maximum clock frequency of 166MHz.

4.7.1.2 Read quad identification

The Read Quad Identification (RDQID_0) transaction provides read access to manufacturer identification, device identification information. This transaction is an alternate way of reading the same information provided by the RDIDN_0_0 transaction while in QPI mode. In all other respects the transaction behaves the same as the RDIDN_0_0 transaction.

The transaction is recognized only when the device is in Quad mode (CFR1V[1] = 1). The instruction is shifted in on DQ0-DQ3. After the last bit of the instruction is shifted into the device, then dummy cycles then, one byte of manufacturer identification and two bytes of device identification will be shifted sequentially out on DQ0-DQ3. Continued shifting of output beyond the end of the defined ID address space will provide undefined data. The maximum clock frequency for the transaction is 166MHz.

4.7.1.3 Read SFDP transaction

The Read Serial Flash Discoverable Parameters (RSFDP_3_0) transaction provides access to the JEDEC Serial Flash Discovery Parameters (SFDP) (see **Transaction table on page 91**). The transaction uses a 3-byte address scheme. If a non-zero address is set, the selected location in the SFDP space is the starting point of the data read. This enables random access to any parameter in the SFDP space. Continuous (sequential) read is supported with the RSFDP_3_0 transaction. Eight latency cycles are required. Read SFDP Transaction is not supported in Read Password mode before the password is provided. The maximum clock frequency for the Read SFDP transaction is 50MHz.

4.7.1.4 Read unique identification transaction

Read Unique Identification (RDUID_0_0) transaction is similar to Read Device Identification transaction, but accesses a different 64-bit number which is unique to each device. It is factory programmed.

4.7.1.5 Read identification related register and transaction

Table 28 Read identification related registers and transactions

Related registers	Related SPI transactions (see Table 73 on page 91)	Related quad SPI transactions (see Table 77 on page 98)

(see Table 50 on page 80)		Read Unique Identification (RDUID_0_0)	
	Read Unique Identification (RDUID_0_0)	Read Quad Manufacturer and Device Identification (RDQID_0_0)	

Features

4.7.2 Read memory array transactions

Memory array data can be read from the memory starting at any byte boundary. Data bytes are sequentially read from incrementally higher byte addresses until the host ends the data transfer by driving CS# input HIGH. If the byte address reaches the maximum address of the memory array, the read will continue at address zero of the array.

4.7.2.1 SPI read and read fast transactions

The SPI Read SDR and Read Fast SDR transactions (1S-1S-1S) are supported for Host systems that require backward compatibility to legacy SPI. Read Fast SDR transaction is available with 3- or 4-byte address options. This protocol does not support the DLP for capture of data. The option of wrapped read length is available. The Read transaction is for maximum clock frequency of 50MHz and requires no latency cycles. The Fast Read Transaction uses latency cycles set by (CFR2V[3:0]) to enable maximum clock frequency of 166MHz (see **Transaction table on page 91**).

The Read Fast 4-Byte transaction has continuous read mode bits that follow the address so, a series of Read Fast 4-Byte transactions can eliminate the eight-bit command after the first Read Fast 4-Byte command sends a mode bit pattern of Axh that indicates the following transaction will also be a Read Fast 4-Byte command. The first Read Fast 4-Byte command in a series starts with the 8-bit command, followed by address, followed by eight cycles of mode bits, followed by an optional latency period. If the mode bit pattern is Axh the next transaction is assumed to be an additional Read Fast 4-Byte transaction that does not provide command bits. That transaction starts with address, followed by mode bits, followed by optional latency. Then the memory contents, at the address given, are shifted out on DQ1_SO.

4.7.2.2 Read SDR dual I/O transaction

The Read SDR Dual I/O transaction provides high data throughput using Dual I/O SDR (1S-2S-2S) protocol. This protocol does not support DLP for capture of data. The option of wrapped read length is available. It supports 3-or 4-byte address options. It supports the mode bits and continuous read transactions. This transaction uses latency cycles set by (CFR2V[3:0]) to enable maximum 166MHz clock frequency (see **Transaction table on page 91**).

4.7.2.3 Read SDR quad output transaction

The Read SDR Quad Output transaction uses the SDR Quad Output (1S-1S-4S) protocol. This protocol supports the DLP for capture of data. The option of wrapped read length is available. It supports 3- or 4-byte address options. This transaction uses latency cycles set by (CFR2V[3:0]) to enable maximum 166MHz clock frequency (see **Transaction table on page 91**).

4.7.2.4 Read SDR and DDR quad I/O transaction

The Read SDR Quad I/O transaction uses the SDR Quad I/O (1S-4S-4S) protocol and Read DDR Quad I/O transaction uses the DDR Quad I/O (1S-4D-4D) protocol. These protocols supports the DLP for capture of data. The option of wrapped read length is available. Both transactions also support the mode bits and continuous read transactions. In SDR Quad I/O transaction, the mode bit pattern is Axh and the next transaction is assumed to be an additional SDR Quad I/O transaction that does not provide command bits.

In DDR Quad I/O transaction, the mode bit pattern is A5h and the next transaction is assumed to be an additional DDR Quad I/O transaction that does not provide command bits. They support 3- or 4-byte address options. These transactions use latency cycles set by (CFR2V[3:0]) to enable maximum 166MHz clock frequency (see **Transaction table on page 91**).

Features

4.7.2.5 **Read QPI SDR and DDR transaction**

The Read QPI SDR transaction uses the SDR QPI(4S-4S-4S) protocol and Read QPI DDR transaction uses the DDR QPI (4S-4D-4D) protocol. These protocols supports the DLP for capture of data. The option of wrapped read length is available. Both transactions also support the mode bits and continuous read transactions. In SDR QPI transaction, the mode bit pattern is Axh and the next transaction is assumed to be an additional SDR OPI transaction that does not provide command bits.

In DDR OPI transaction, the mode bit pattern is A5h and the next transaction is assumed to be an additional DDR QPI transaction that does not provide command bits. They support 3- or 4-byte address options. These transactions use latency cycles set by (CFR2V[3:0]) to enable maximum 166MHz clock frequency (see Transaction table on page 91).

	-	-	Continuous Read QPI DDR (RDAY8_4_0, RDAY8_C_0)

4.7.3 **Read registers transactions**

There are multiple registers for reporting embedded operation status or controlling device configuration options. Registers contain both volatile and nonvolatile bits. There are two ways to read the Registers. The Read Any Register transaction provides a way to read all device registers: nonvolatile and volatile by address selection. There are also dedicated Register Read transactions, which are defined per register and only read the contents of that register.

4.7.3.1 Read any register

The Read Any Register (RDARG_C_0) transaction is the best way to read all device registers, both nonvolatile and volatile. The transaction includes the address of the register to be read (see Transaction table on page 91). This is followed by a number of latency cycles set by (CFR2V[3:0]) for reading nonvolatile registers and CFR3V[7:6] for reading volatile registers. See Table 49 for NV Registers latency cycles and Table 51 for Volatile Registers latency cycles. Then, the selected register contents are returned. If the read access is continued, the same addressed register contents are returned until the transaction is terminated; only one byte register location is read by each RDARG_C_0 transaction. For registers with more that one byte of data, the RDARG_C_0 transaction must again be used to read each byte of data.

The maximum clock frequency for the RDARG_C_0 transaction is 166MHz.

The RDARG C 0 transaction can be used during embedded operations to read Status Register 1 (STR1V). It is not used for reading registers such as ASP PPB Access Register (PPAV) and ASP Dynamic Block Access Register (DYAV). There are separate commands required to select and read the location in the array accessed. The RDARG_C_0 transaction will read invalid data from the PASS Register locations if the ASP Password protection mode is selected by programming ASPR[2:0]. Reading undefined locations provides undefined data.

Features

4.7.3.2 Read status registers transaction

The Read Status Register (RDSR1_0_0, RDSR2_0_0) transactions allow the Status Registers' volatile contents to be read. The transaction uses latency cycles set by (CFR3V[7:6]) for reading volatile registers to enable maximum clock frequency of 166MHz.

The volatile version of Status Registers contents can be read at any time, even while a program, erase, or write operation is in progress.

It is possible to read Status Register 1 continuously by providing multiples of eight clock cycles. The status is updated for each eight cycle read.

4.7.3.3 Read configuration register transaction

The Read Configuration Register (RDCR1_0_0) transaction allows the Configuration registers volatile contents be read. The transaction uses latency cycles set by (CFR3V[7:6]) for reading volatile registers to enable maximum clock frequency of 166MHz.

The volatile version of Status Registers contents can be read at any time, even while a program, erase, or write operation is in progress.

It is possible to read Configuration Registers continuously by providing multiples of eight clock cycles. The status is updated for each eight cycle read.

4.7.3.4 Read dynamic protection bit (DYB) access register transaction

The Read DYB Access Register (RDDYB_4_0,RDDYB_C_0) transaction reads the contents of the DYB Access Register. The transaction uses latency cycles set by (CFR3V[7:6]) for reading volatile registers to enable maximum clock frequency of 166MHz. It is possible to read DYB Access register continuously, however the address of the DYB register does not increment, so the entire DYB array cannot be read in this fashion. Each location must be read with a separate Read DYB transaction.

4.7.3.5 Read persistent protection bit (PPB) access register transaction

The Read PPB Access Register (RDPBB_4_0,RDPBB_C_0) transaction reads the contents of the PPB Access Register. The transaction uses latency cycles set by (CFR2V[3:0]) to enable maximum clock frequency of 166MHz. It is possible to read PPB Access Register continuously, however the address of the PPB register does not increment, so the entire PPB array cannot be read in this fashion. Each location must be read with a separate Read PPB transaction.

4.7.3.6 Read PPB lock registers transaction

The Read PPB Lock Register (RDPLB_0_0) transactions allow the content of the nonvolatile registers to be read. The transaction uses latency cycles set by (CFR3V[7:6]) for reading volatile registers to enable maximum clock frequency of 166MHz. It is possible to read PPB Lock Bit continuously.

4.7.3.7 Read ECC data unit status

The Read ECC Data Unit Status (RDECC_4_0, RDECC_C_0) transaction is used to determine the ECC status of the addressed unit data. In this transaction, the LSb of the address must be aligned to an ECC data unit. This transaction uses latency cycles set by (CFR3V[7:6]) for reading volatile registers to enable maximum clock frequency of 166MHz.

The byte contents of the ECC Status for the selected ECC unit is then output. Any following data will be indeterminate. To read the next ECC unit status, another RDECC_4_0 or RDECC_C_0 transaction should be sent out to the next address, incremented by 16 [Data Unit size/8] bytes.

4.7.4 Data learning pattern (DLP)

The device supports Data Learning Pattern (DLP) which allows the host controller to optimize the data capture window. The READ preamble training is only available in Quad Mode READs. The programmable training pattern is stored in a DLP Register. To enable training, a non-zero pattern must be stored in the DLP Register. The device outputs the pattern during the latency cycles. Bus Turnaround between the end of the address input by the host and the pattern output by the device is not a concern since the first three latency clock cycles are treated as dummy cycles. All IO signals transition the same data learning pattern bits.

The device outputs the learning pattern during latency cycles. The pattern driven on the IO signals depends on the number of latency cycles available for the READ transaction. If the latency is set to at least 9 clock cycles for SDR operation, the device will output the pattern on the IOs on the last 8 clock cycles before outputting the READ data. However, if the latency is set to less than 9 clock cycles, no data learning pattern is outputted. If the latency is set to at least 5 clock cycles for DDR operation, the device will output the pattern on the IOs on the last 4 clock cycles before outputting the READ data. However, if the latency is set to less than 4 clock cycles, no data learning pattern is outputted.

Quad SPI, 1.8V/3.0V

Features

4.8 Write

There are write transactions for writing to the Registers. These write transactions can use the SPI and Quad SPI protocols as mentioned in the Transaction Protocols section:

4.8.1 Write enable transaction

The Write Enable (WRENB_0_0) transaction sets the Write Program Enable Status (WRPGEN) bit of the Status Register 1 (STR1V[1]) to 1. The WRPGEN bit must be set to 1 by issuing the Write Enable (WRENB_0_0) Transaction to enable write, program, and erase transactions (see **Transaction table on page 91**).

4.8.2 Write enable for volatile registers

The volatile Status and Configuration registers, can be written by sending the WRENV_0_0 transaction followed by any write register transactions. This gives more flexibility to change the system configuration and memory protection schemes quickly without waiting for the typical nonvolatile bit write cycles or affecting the endurance of the status or configuration nonvolatile register bits. The WRENV_0_0 transaction is used only to direct the following write register transaction to change the volatile status and configuration register bit values.

4.8.3 Write disable transaction

The Write Disable (WRDIS_0_0) transaction clears the Write Program Enable Status (WRPGEN) bit of the Status Register 1 (STR1V[1]) to 0.

The WRPGEN bit can be cleared to 0 by issuing the Write Disable (WRDIS_0_0) transaction to disable commands that requires WRPGEN be set to 1 for execution. The WRDIS_0_0 transaction can be used by the user to protect memory areas against inadvertent write, program, or erase operations that can corrupt the contents of the memory. The WRDIS_0_0 transaction is ignored during an embedded operation while RDYBSY bit = 1 (STR1V[0]) (see **Transaction table on page 91**).

4.8.4 Clear program and erase failure flags transaction

The Clear Program and Erase Failure Flags (CLPEF_0_0) transaction resets bit STR1V[5] (Erase Error Flag) and bit STR1V[6] (Program Error Flag) to 0. This transaction will be accepted even when the device remains busy with RDYBSY set to 1, as the device does remain busy when either error bit is set. The WRPGEN bit will be unchanged after this transaction is executed (see **Transaction table on page 91**).

4.8.5 Clear ECC status register transaction

The Clear ECC Status Register (CLECC_0_0) transaction resets bit ECSV[4] (2-bit ECC Detection), bit ECSV[3] (1-bit ECC Correction), INSV[1:0] ECC detection status bits, Address Trap Register EATV[31:0], and ECC Detection Counter ECTV[15:0]. It is not necessary to set the WRPGEN bit before this transaction is executed. The Clear ECC Status Register transaction will be accepted even when the device remains busy with WRPGEN set to 1, as the device does remain busy when either error bit is set. The WRPGEN bit will be unchanged after this command is executed (see **Transaction table on page 91**).

4.8.6 Write registers transactions

The Write Registers (WRREG_0_1) transaction allows new values to be written to both the Status and Configuration Registers. Before the Write Registers transaction can be accepted by the device, a Write Enable or Write Enable for Volatile Registers transaction must be received. After the Write Enable command has been decoded successfully, the device will set the WRPGEN in the Status Register to enable any write operations.

The Write Registers transaction is entered by shifting the instruction and the data bytes on DQ0_SI. The Status and Configuration Registers are one data byte in length.

The WRR operation first erases the register then programs the new value as a single operation. The Write Registers transaction will set the PRGERR or ERSERR bits if there is a failure in the WRREG_0_1 operation.

Features

4.8.7 Write any register transaction

The Write Any Register (WRARG_C_1) transaction provides a way to write any device register, nonvolatile or volatile. The transaction includes the address of the register to be written, followed by one byte of data to write in the addressed register (see **Transaction table on page 91**).

Before the WRARG_C_1 transaction can be accepted by the device, a Write Enable (WRENB_0_0) transaction must be issued and decoded, which sets the Write/Program Enable bit (WRPGEN) in the Status Register to enable any write operations. The RDYDSY bit in STR1V[0] can be checked to determine when the operation is completed. The PRGERR and ERSERR bits in STR1V[6:5] can be checked to determine if any error occurred during the operation.

Some registers have a mixture of bit types and individual rules controlling which bits can be modified. Some bits are read only, some are OTP, and some are designated Reserved (DNU).

Read only bits are never modified and the related bits in the WRARG_C_1 transaction data byte are ignored without setting a program or erase error indication (PRGERR or ERSERR in STR1V[6:5]). Hence, the value of these bits in the WRARG_C_1 data byte do not matter.

OTP bits can only be programmed to the level opposite of their default state. Writing of OTP bits back to their default state is ignored and no error is set.

Nonvolatile bits which are changed by the WRARG_C_1 data, require nonvolatile register write time (t_W) to be updated. The update process involves an erase and a program operation on the nonvolatile register bits. If either the erase or program portion of the update fails, the related error bit and RDYBSY bit in STR1V will be set to 1.

Status Register 1 can be repeatedly read (polled) to monitor the RDYBSY bit (STR1V[0]) and the error bits (STR1V[6,5]) to determine when the register write is completed or failed. If there is a write failure, the CLPEF_0_0 transaction is used to clear the error status and enable the device to return to standby state.

The ASP PPB Lock Register (PPLV) register cannot be written by the WRARG_C_1 transaction. Only the Write PPB Lock Bit (WRPLB_0_0) transaction can write the PPLV Register.

The Data Integrity Check Register cannot be written by the WRARG_C_1 transaction. The Data Integrity Check Register is loaded by running the Data Integrity Check transaction (DICHK_4_1).

4.8.8 Write PPB lock bit

The Write PPB Lock Bit (WRPLB_0_0) transaction clears the PPB Lock Register PPLV[0] to zero. The PPBLCK bit is used to protect the PPB bits. When PPLV[0] = 0, the PPB Program/Erase transaction will be aborted. In Read Password Protection mode, PPBLCK bit is also used to control the high order bits of the address by forcing the address range to be limited to one sector where boot code is stored, until the read password is supplied (see **Transaction table on page 91**).

Before the WRPLB_0_0 transaction can be accepted by the device, a Write Enable (WRENB_0_0) transaction must be issued and decoded by the device, which sets the Write/Program Enable (WRPGEN) in the Status Register 1 to enable any write operations.

While the operation is in progress, the Status Register can still be read to check the value of the RDYBSY bit. The WRPGEN bit is a 1 during the self-timed operation, and is a 0 when it is completed. When the Write PPB Lock transaction is completed, the RDYBSY bit is set to a 0 (see **Transaction table on page 91**).

4.9 Program

There are program transactions for programming data to the Memory Array, Secure Silicon Region and Persistent Protection Bits.

These program transactions can use SPI or Quad SPI protocols:

Before any program transaction can be accepted by the device, a Write Enable (WRENB_0_0) transaction must be issued and decoded by the device. Program transactions can only be executed by the device if the Write/Program Enable (WRPGEN) in the Status Register is set to '1' to enable program operations. When a program transaction is completed, the WRPGEN bit is reset to a '0'.

While the program transaction is in progress, the Status Register 1 may be read to check the value of the Device Ready/Busy (RDYBSY) bit. The RDYBSY bit is a '1' during the self-timed program transaction, and is a '0' when it is completed.

The PGMERR bit in STR1V[6] may be checked to determine if any error occurred during the program transaction.

A program transaction applied to a sector that has been Write Protected through any of the protection schemes, will not be executed and will set the PGMERR status fail bit.

The program transactions will be initiated when CS# is driven into the logic HIGH state.

4.9.1 Program granularity

The HS/L-T family supports multi-pass programming (bit walking) where programming a "0" over a "1" without performing the sector erase operation. Bit-walking is allowed for the non-AEC-Q100 industrial temperature range (-40° C to +85°C) of this device. It is required to perform only one programming operation (single-pass programming) on each ECC data unit between erase operations for the higher temperature range (-40° C to +105°C) and (-40° C to +125°C) devices and all AEC-Q100 devices.

Multi-pass programming without an erase operation will disable the device's ECC functionality for that data unit. Note that if 2-bit ECC is enabled, multi-pass Programming within the same sector will result in a Program Error.

4.9.2 Page programming

Page Programming is done by loading a Page Buffer with data to be programmed and issuing a programming transaction to move data from the buffer to the memory array. This sets an upper limit on the amount of data that can be programmed with a single programming transaction. Page Programming allows up to a page size (either 256- or 512-bytes) to be programmed in one operation. The page size is determined by the Configuration Register 3 bit CFR3V[4]. The page is aligned on the page size address boundary. It is possible to program from one bit up to a page size in each Page Programming operation. It is recommended that a multiple of 16-byte length and aligned Program Blocks be written. This ensures that ECC is not disabled. For the very best Page Program throughput, programming should be done in full pages of 512 bytes aligned on 512-byte boundaries with each Page being programmed only once.

Features

4.9.3 Program page transaction

The Program Page transaction (PRPGE_4_1, PRPGE_C_1) programs data into the memory array. If data more than a page size (256B or 512B) is sent to the device, then the space between the starting address and the page aligned end boundary, the data loading sequence will wrap from the last byte in the page to the zero byte location of the same page and begin overwriting any data previously loaded in the page. If less than a page of data is sent to the device, then the sent data bytes will be programmed in sequence, starting at the provided address within the page, without having any effect on the other bytes of the same page. The programming process is managed by the device internal control logic. The PRGERR bit indicates if an error has occurred in the programming transaction that prevents successful completion of programming. This includes attempted programming of a protected area (see **Transaction table on page 91**).

4.9.4 Program secure silicon region transaction

The Program Secure Silicon transaction (PRSSR_C_1) programs data in the SSR, which is in a different address space from the main array data and is OTP. The SSR is 1024 bytes, so the address bits from A31 to A10 must be zero for this transaction (see **Transaction table on page 91**). It is required to align start address to 32 bits while programming SSR space, which means the address bits A1 and A0 should be 0'b and host should deassert CS# to align with 32 bits.

The PRGERR bit in STR1V[6] may be checked to determine if any error occurred during the operation.

To program the OTP array in bit granularity, the rest of the bits within a data byte can be set to 1.

Each SSR memory space can be programmed one or more times, provided that the region is not locked. Attempting to program zeros in a region that is locked will fail with the PRGERR bit in STR1V[6] set to 1. Programming once, even in a protected area does not cause an error and does not set PRGERR bit. Subsequent programming can be performed only on the unprogrammed bits (that is, 1 data). Programming more than once within an ECC unit will disable ECC on that data unit.

4.9.5 Program persistent protection bit (PPB)

The Program Persistent Protect Bit (PRPPB_4_0, PRPPB_C_0) transaction programs a bit in the PPB Register to protect the sector of the provided address from being programed or erased (see **Transaction table on page 91**).

The PRGERR bit in STR1V[6] may be checked to determine if any error occurred during the operation. Program PPB bit transaction will abort when trying to program the PPB bits protected by ASPPPB (ASPO[3]), ASPPRM (ASPO[0]) and PPBLCK (PPLV[0]) bit.

4.9.6 Program related registers and transactions

Quad SPI, 1.8V/3.0V

Features

4.10 Erase

There are erase transactions for erasing data bits to 1 (all bytes are FFh) for the Memory Array and Persistent Protection Bits.

Before any erase transaction can be accepted by the device, a Write Enable (WRENB_0_0) transaction must be issued and decoded by the device. Erase transactions can only be executed by the device if the Write/Program Enable bit (WRPGEN) in the Status Register is set to '1' to enable erase operations. When an erase transaction is completed, the WRPGEN bit is reset to a '0'.

While the erase transaction is in progress, the Status Register 1 may be read to check the value of the Device Ready/Busy (RDYBSY) bit. The RDYBSY bit is a '1' during the self-timed erase transaction, and is a '0' when it is completed.

The ERSERR bit in STR1V[5] can be checked to determine if any error occurred during the erase transaction.

An erase transaction applied to a sector that has been Write Protected through the Block Protection bits or ASP, will not be executed and will set the ERSERR status fail bit.

Erase transactions will be initiated when CS# is driven into the logic HIGH state.

When the device is shipped from the factory the default erase state is all bytes are FFh.

4.10.1 Erase 4KB sector transaction

The Erase 4KB Sector (ER004_4_0, ER004_C_0) transaction sets all the bits of a 4KB sector to 1 (all bytes are FFh) (see **Transaction table on page 91**).

This transaction is ignored when the device is configured for uniform sectors only (CFR3V[3] = 1). If the Erase 4KB sector transaction is issued to a non-4KB sector address, the device will abort the operation and will not set the ERSERR status fail bit.

4.10.2 Erase 256KB sector transaction

The Erase 256KB Sector (ER256_4_0, ER256_C_0) transaction sets all bits in the addressed sector to 1 (all bytes are FFh) (see **Transaction table on page 91**).

A device configuration option (CFR3V[3]) determines if the Hybrid Sector Architecture is in use. When CFR3V[3] = 0, 4KB sectors overlay a portion of the highest or lowest address 128KB or 64KB of the device address space. If a sector erase transaction is applied to a 256KB sector that is overlaid by 4KB sectors, the overlaid 4KB sectors are not affected by the erase. Only the visible (non-overlaid) portion of the 128KB or 192KB sector is erased. When CFR3V[3] = 1, there are no 4KB sectors in the device address space and the Sector Erase transaction always operates on fully visible 256KB sectors.

When BLKCHK is enabled an erase transaction first evaluates the erase status of the sector. If the sector is found to erased, the erase operation is aborted. The erase operation is only executed if programmed bits are found in the sector. Disabling BLKCHK executes an erase operation unconditionally.

4.10.3 Erase chip transaction

The Erase Chip (ERCHP_0_0) transaction sets all bits to 1 (all bytes are FFh) inside the entire flash memory array (see **Transaction table on page 91**).

An Erase Chip transaction can be executed only when the Block Protection (BP2, BP1, BP0) bits are set to 0's. If the BP bits are not zero, the transaction is not executed and ERSERR status fail bit is not set. The transaction will skip any sectors protected by the Advance Sector Protection DYB or PPB and the ERSERR status fail bit will not be set.

4.10.4 Erase persistent protection bit (PPB) transaction

The Erase PPB transaction (ERPPB_0_0) sets all PPB bits to 1 (see **Transaction table on page 91**). This transaction will abort if PPB bits are protected by ASPPPB (ASPO[3]), ASPPRM (ASPO[0]) and PPBLCK (PPLV[0]) bit.

4.10.5 Erase status and count

4.10.5.1 Evaluate erase status transaction

The Evaluate Erase Status (EVERS_C_0) transaction verifies that the last erase operation on the addressed sector was completed successfully. If the selected sector was successfully erased, then the erase status bit (STR2V[2]) is set to 1. If the selected sector was not completely erased STR2V[2] is 0. The Write/Program Enable transaction (to set the WRPGEN bit) is not required before this transaction. However, the RDYBSY bit is set by the device itself and cleared at the end of the operation, as visible in STR1V[0] when reading status (see **Transaction table on page 91**).

The Evaluate Erase Status transaction can be used to detect when erase operations that have failed due to loss of power, reset, or failure during the erase operation. The transaction requires t_{EES} to complete and update the erase status in STR2V. The RDYBSY bit (STR1V[0]) can be read to determine when the Evaluate Erase Status transaction is completed. If a sector is found not erased with STR2V[2] = 0, the sector must be erased again to ensure reliable storage of data in the sector.

4.10.5.2 Sector erase count transaction

The Sector Erase Count (SEERC_C_0) transaction outputs the number of erase cycles for the addressed sector. The erase cycle count is stored in the Sector Erase Count (SECV[22:0]) Register, and can be read by using the Read Any Register transaction (RDARG_C_0). The RDYBSY bit is set by the device itself and cleared at the end of the operation, as visible in STR1V[0] when reading status (see **Transaction table on page 91**).

The transaction requires t_{SEC} to complete and update the SECV[22:0] Register. The RDYBSY bit (STR1V[0]) may be read to determine when the Sector Erase Count Transaction finished. The SECV[23] bit is used to determine if the reported sector erase count is corrupted and was reset.

Features

4.11 Suspend and resume embedded operation

HL-T/HS-T device can interrupt and suspend the running embedded operations such as Erase, Program, or Data Integrity Check. It can also resume the suspended operation once the host finishes the intermediate operation and sends the respective resume transaction to the device.

4.11.1 Erase, program, or data integrity check suspend

The Suspend transaction allows the system to interrupt a program, erase, or data integrity check operation and then read from any other non erase-suspended sector, non-program-suspended-page or the array. The Device Ready/Busy Status Flag (RDYBSY) in Status Register 1 (STR1V[0]) must be checked to know when the program, erase, or data integrity check operation has stopped.

4.11.1.1 Program suspend

- Program Suspend is valid only during a programming operation.
- The Program Operation Suspend Status flag (PROGMS) in Status Register-2 (STR2V[0]) can be used to determine if a programming operation has been suspended or was completed at the time RDYBSY changes to 0.
- A program operation can be suspended to allow a read operation.
- Reading at any address within a program-suspended page produces undetermined data.

4.11.1.2 Erase suspend

- Erase Suspend is valid only during a sector erase operation.
- The Erase operation Suspend status flag (ERASES) in Status Register-2 (STR2V[1]) can be used to determine if an erase operation has been suspended or was completed at the time RDYBSY changes to 0.
- A Chip Erase operation cannot be suspended.
- An Erase operation can be suspended to allow a program operation or a read operation.
- During an erase suspend, the DYB array can be read to examine sector protection.
- A new erase operation is not allowed with an already suspended erase, program, or data integrity check operation. An erase transaction is ignored in this situation.
- Reading at any address within an erase-suspended sector produces undetermined data.

4.11.1.3 Data Integrity Check Suspend

- Data Integrity Check Suspend is valid only during a Data Integrity Check Calculation operation.
- The Memory Array Data Integrity Cyclic Redundancy Check Suspend Status Flag (DICRCS) in Status Register-2 (STR2V[4]) can be used to determine if a data integrity check operation has been suspended or was completed at the time RDYBSY changes to 0.
- A data integrity check operation can be suspended to allow a read operation.

The Write Any Register or Erase Persistent Protection Bit transactions are not allowed during Erase, Program, or Data Integrity Check Suspend. It is therefore not possible to alter the Block Protection or PPB bits during Erase Suspend. If there are sectors that may need programming during Erase suspend, these sectors should be protected only by DYB bits that can be turned OFF during Erase Suspend.

The time required for the suspend operation to complete is t_{PEDS} .

After an erase-suspended program operation is complete, the device returns to the erase-suspend mode. The system can determine the status of the program operation by reading the RDYBSY bit in the Status Register 1, just as in the standard program operation.

Features

Table 35 lists the transactions allowed during the suspend operation.

Transactions allowed during suspend Table 35

Transaction name	Allowed during erase suspend	Allowed during program suspend	Allowed during data integrity check suspend
Write Disable (WRDIS_0_0)		No	No
Read Status Register 1 (RDSR1_0_0)		Yes	Yes
Write Enable (WRENB_0_0)		No	No
Write Enable Volatile (WRENV_0_0)		No	No
Read Status Register 2 (RDSR2_0_0)		Voc	Voc
Read Configuration Register 1 (RDCR1_0_0)		Yes	Yes
Program Page (PRPGE_4_1, PRPGE_C_1)		No	No
Read ECC Status (RDECC_4_0, RDECC_C_0)			
Clear ECC Status Register (CLECC_0_0)			
Read PPB Lock Bit (RDPLB_0_0)		Yes	Yes
Resume Program / Erase / Data Integrity Check (RSEPD_0_0)			
Resume Program / Erase (RSEPA_0_0)			
Program SSR (PRSSR_C_1)		No	No
Read SSR (RDSSR_C_0)	1	Yes	
Read Unique ID (RDUID_0_0)	1		
Read SFDP (RSFDP_3_0)			
Read Quad Manufacturer and device Identification (RDQID_0_0)	Yes		
Read Any Register (RDARG_C_0)			
Software Reset Enable (SRSTE_0_0)		Yes	Yes
Clear Program and Erase Failure Flags (CLPEF_0_0)		1.00	
Software Reset (SFRST_0_0)			
Legacy Software Reset (SFRSL_0_)			
Read Identification Register (RDIDIN_0_0) (manufacturer and device identification)			
Suspend Program / Erase / Data Integrity Check (SPEPD_0_0)		No	No
Suspend Program / Erase (SPEPA_0_0)		No	No
Read DYB (RDDYB_4_0, RDDYB_C_0)			Yes
Read PPB (RDPPB_4_0, RDPPB_C_0)			
Read SDR (RDAY1_C_0, RDAY1_4_0)			
Read Fast SDR (RDAY2_C_0, RDAY2_4_0)		Yes	
Read SDR Dual I/O (RDAY3_C_0, RDAY3_4_0)			
Read SDR Quad Output (RDAY4_C_0, RDAY4_4_0)			
Read SDR Quad I/O (RDAY5_C_0, RDAY5_4_0)			
Read DDR Quad I/O (RDAY7_C_0, RDAY7_4_0)	Voc	Voc	Voc
Read Data Learning Pattern (RDDLP_0_0)	Yes	Yes	Yes

4.11.2 Erase, program, or data integrity check resume

An Erase, Program, or Data Integrity Check Resume transaction must be written to resume a suspended operation. After program or read operations are completed during a Program, Erase or Data Integrity Check suspend, the Resume transaction is sent to resume the suspended operation.

After an Erase, Program, or Data Integrity Check Resume transaction is issued, the RDYBSY bit in Status Register 1 will be set to a 1 and the programming operation will resume if one is suspended. If no program operation is suspended, the suspended erase operation will resume. If there is no suspended program, erase or data integrity check operation, the resume transaction is ignored.

Program, Erase, or Data Integrity Check operations may be interrupted as often as necessary. For example, a program suspend transaction could immediately follow a program resume transaction, but for a program or erase operation to progress to completion there must be some period of time between resume and the next suspend transaction greater than or equal to $t_{\rm PEDRS}$.

Figure 55 shows the flow of suspend and resume operation.

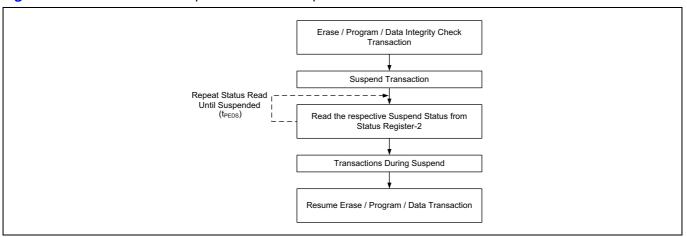

Figure 55 Suspend and resume sequence

Quad SPI, 1.8V/3.0V

Features

4.12 Reset

HL-T/HS-T devices support four types of reset mechanisms.

- Hardware Reset (using RESET# input pin and DQ3_RESET# pin)
- Power-on reset (POR)
- · CS# signaling reset
- · Software Reset

4.12.1 Hardware reset (using RESET# input pin and DQ3_RESET# pin)

The RESET# input initiates the reset operation with a transition from logic HIGH to logic LOW for > t_{RP} , and causes the device to perform the full reset process that is performed during POR. The hardware reset process requires a period of t_{RH} to complete. See **Table 84** for timing specifications.

The DQ3_RESET# input initiates the reset operation under the following when CS# is HIGH for more than tcs time or when Quad or QPI mode is not enabled. The DQ3_RESET# input has an internal pull-up to Vcc and may be left unconnected if Quad or QPI mode is not used. The tcs delay after CS# goes HIGH gives the memory or host system time to drive DQ3 HIGH after its use as a Quad or QPI mode I/O signal while CS# was LOW. The internal pull-up to Vcc will then hold DQ3_RESET# HIGH until the host system begins driving DQ3_RESET#. The DQ3_RESET# input is ignored while CS# remains HIGH during tcs, to avoid an unintended Reset operation. If CS# is driven LOW to start a new transaction, DQ3_RESET# is used as DQ3.

When the device is not in Quad or QPI mode or, when CS# is HIGH, and DQ3_RESET# transitions from $V_{\rm IL}$ to $V_{\rm IH}$ for > trp, following tcs, the device will reset register states in the same manner as POR. The hardware reset process requires a period of trh to complete. If the POR process did not complete correctly for any reason during power-up (tru), RESET# going LOW will initiate the full POR process instead of the hardware reset process and will require tru to complete the POR process.

Additional DO3 RESET# notes

- If both RESET# and DQ3_RESET# input options are available use only one reset option in your system. DQ3_RESET# input reset operation can be disable by setting CFR2N[5] = 0 setting the DQ3_RESET to only operate as DQ3. The RESET# input can be disable by not connecting or tying the RESET# input to VIH. RESET# and DQ3_RESET# must be HIGH for tRs following tPU, before going LOW again to initiate a hardware reset.
- When DQ3_RESET# is driven LOW for at least a minimum period of time (trp), following tcs, the device terminates any operation in progress, makes all outputs high impedance, and ignores all read/write transactions for the duration of transactions for the interface to standby state.
- If Quad or QPI mode and the DQ3_RESET# feature are enabled, the host system should not drive DQ3 LOW during tcs, to avoid driver contention on DQ3. Immediately following transactions that transfer data to the host in Quad or QPI mode, for example: Quad I/O Read, the memory drives DQ3_RESET# HIGH during tcs, to avoid an unintended Reset operation. Immediately following transactions that transfer data to the memory in Quad mode, for example: Page Program, the host system should drive DQ3_RESET# HIGH during tcs, to avoid an unintended Reset operation.DQ3_RESET# LOW is ignored during tcs if Quad mode is enabled.

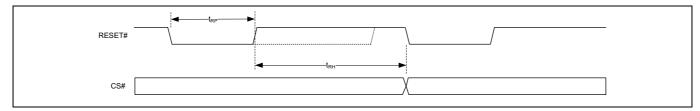

Figure 58 Hardware reset using RESET# input (Back to back hardware reset)

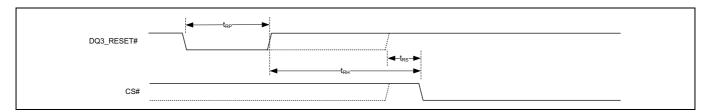

Figure 59 Hardware reset when quad or QPI Mode is disabled and DQ3_RESET# is enabled

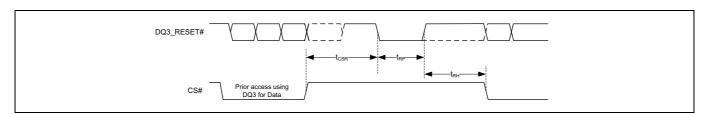

Figure 60 Hardware reset when quad or QPI Mode and DQ3_RESET# are enabled

4.12.2 Power-on reset (POR)

The device executes a POR process until a time delay of t_{PU} has elapsed after the moment that V_{CC} rises above the minimum V_{CC} threshold (see **Figure 61** and **Figure 62**). The device must not be selected during power-up (t_{PU}) . Therefore, CS# must rise with V_{CC} . No transactions may be sent to the device until the end of t_{PU} . See **Table 84** for timing specifications.

RESET# is ignored during POR. If RESET# is LOW during POR and remains LOW through and beyond the end of t_{PU} , CS# must remain HIGH until t_{RS} after RESET# returns HIGH.

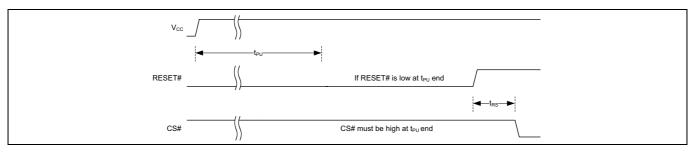

Figure 61 Reset LOW at the end of POR

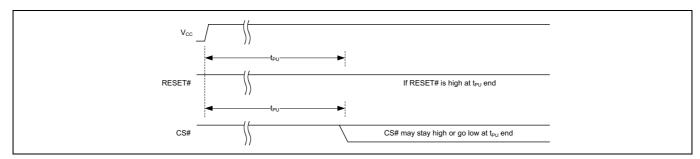

Figure 62 Reset HIGH at the end of POR

4.12.3 CS# signaling reset

The CS# Signaling Reset requires CS# and DQ0 signals. This reset method defines a signaling protocol, using existing signals, to initiate an SPI flash hardware reset, independent of the device operating mode or number of package pins.

The Signaling Protocol is shown in **Figure 63**. See **Table 84** for timing specifications. The CS# signaling reset steps are as follows:

- CS# is driven active LOW.
- CK remains stable in either HIGH or LOW state.
- CS# and DQ0 are both driven LOW.
- CS# is driven HIGH (inactive).
- Repeat the above four steps, each time alternating the state of DQ0 for a total of four times.
- Reset occurs after the fourth CS# cycle completes and it goes HIGH (inactive).

After the fourth CS# pulse, the slave triggers its internal reset, the device terminates any operation in progress, makes all outputs high impedance, and ignores all read/write transactions for the duration of $t_{\sf RESET}$. Then the device will be in standby state.

256Mb/512Mb/1Gb SEMPER™ Flash

Quad SPI, 1.8V/3.0V

Features

This reset sequence is not intended to be used at normal power on, but to be used only when the device is not responding to the system. This reset sequence will be operational from any state that the device may be in. Hence, CS# signaling reset is useful for packages that don't support a RESET# pin to provide behavior identical to Hardware Reset.

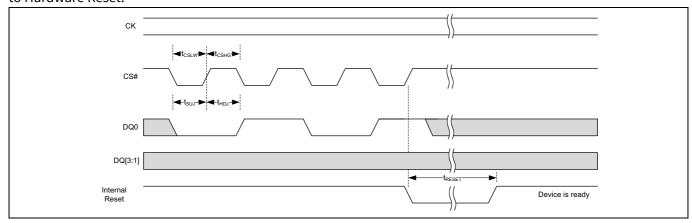

Figure 63 CS# signaling reset protocol

4.12.4 Software reset

Software controlled Reset transaction restores the device to its initial power up state, by reloading volatile registers from nonvolatile default values except the protection registers. It also terminates the embedded operations. A reset transaction (SFRST_0_0) is executed when CS# is brought HIGH at the end of the transaction and requires tsR time to execute. See **Table 84** for timing specifications.

The Reset Enable (SRSTE_0_0) transaction is required immediately before a Reset transaction (SFRST_0_0) such that a software reset is a sequence of the two transactions. Any transaction other than SFRST_0_0 following the SRSTE_0_0 transaction will clear the reset enable condition and prevent a later SFRST_0_0 transaction from being recognized.

The Reset (SFRST_0_0) transaction immediately following a SRSTE_0_0 transaction, initiates the software reset process. During software reset, only RDSR1_0_0 and RDARG_C_0 of Status Register 1 are supported operations as long as the volatile and nonvolatile configuration states of the device are the same. If the configuration state is changing during software reset, reading Status Register 1 should only be done after the software reset time has elapsed.

The software reset is independent of the state of RESET#. If RESET# is HIGH or Unconnected, and the software reset transactions are issued, the device will perform software reset.

The Legacy Software Reset (SFRSL_0_0) is a single transaction that initiates the software reset process. This command is disabled by default but can be enabled by programming CFR3V[0] = 1, for software compatibility with CYPRESSTM legacy devices.

4.13 Power modes

4.13.1 Active power and standby power modes

The device is enabled and in the Active Power mode when Chip Select (CS#) is LOW. When CS# is HIGH, the device is disabled, but may still be in an Active Power mode until all program, erase, and write operations have completed. The device then goes into the Standby Power mode, and power consumption drops to I_{SB}. See Table 82 for parameter specifications.

4.13.2 Deep power down (DPD) mode

Although the standby current during normal operation is relatively low, standby current can be further reduced with the DPD mode. The lower power consumption makes the DPD mode especially useful for battery powered applications.

4.13.2.1 Enter DPD

The device can enter DPD mode in two ways:

- 1. Enter DPD Mode using Transaction
- 2. Enter DPD Mode upon Power-up or Reset

Enter DPD Mode using the Enter Deep Power Down Mode Transaction

The DPD mode is enabled by sending the Enter Deep Power Down Mode Transaction (ENDPD_0_0) then waiting for a delay of $t_{\rm ENTDPD}$. The CS# pin must be driven HIGH after the command byte has been latched. If this is not done, then the DPD transaction will not be executed. After CS# is driven HIGH, the power-down state will be entered within the time duration of $t_{\rm ENTDPD}$ (see **Table 84** for timing specifications) and power consumption drops to $t_{\rm DPD}$. See **Table 82** for parameter specifications.

DPD can only be entered from an idle state. The DPD transaction is accepted only while the device is not performing an embedded algorithm as indicated by the Status Register 1 volatile, Device Ready/Busy Status Flag (RDYBSY) bit being cleared to zero (STR1V[0] = RDYBSY = 0). It is not allowed to send any transaction to device during t_{ENTDPD} time.

Enter DPD Mode upon Power-up or Reset

If the DPDPOR configuration bit is enabled (CFR4NV[2] = 1), the device will be in DPD mode after the completion of Power-up, Hardware Reset or CS# Signaling Reset. During POR or Reset the CS# should follow the voltage applied on VCC to enter DPD mode as shown in **Figure 64**. It is not allowed to send any transaction to device during t_{FNTDPD} time.

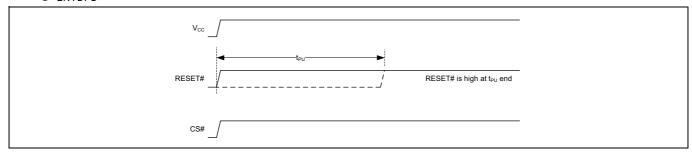

Figure 64 Enter DPD mode upon power-up or reset

4.13.2.2 Exit DPD

Device leaves DPD mode in one of the following ways:

Exit DPD Mode upon Hardware Reset

When the device is in DPD and CFR4NV[2] = 0, a Hardware reset will return the device to Standby mode.

Exit DPD Mode upon CS# Pulse

Device exits DPD upon receipt of CS# pulse of width t_{CSDPD} . The CS# should be driven HIGH after the pulse. HIGH to LOW transition on CS# is required to start a transaction cycle after the DPD exit. It takes t_{EXTDPD} to come out of DPD mode. The device will not respond until after t_{EXTDPD} .

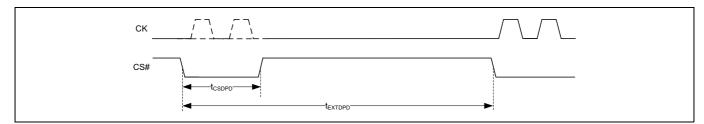

Figure 65 Exit DPD mode

The device maintains its configuration during DPD, meaning the device exits DPD in the same state as it entered. Registers such as the ECC Status, ECC Error Detection Counter, Address Trap, and Interrupt Status Registers will be cleared.

4.13.2.3 DPD related registers and transactions

Table 39 Erase related registers and transactions

Related registers	Related SPI transactions (see Table 73 on page 91)	Related quad SPI transactions (see Table 77 on page 98)
Configuration Register 4 (CFR4N, CFR4V) (see Table 52 on page 81)	Enter Deep Power Down Mode (ENDPD_0_0)	Enter Deep Power Down Mode (ENDPD_0_0)

4.14 Power up and power down

The device must not be selected at power up or power down until V_{CC} reaches the correct value as follows:

- V_{CC} (min) at power up, and then for a further delay of t_{PU}
- V_{SS} at power down

4.14.1 Power up

The device ignores all transactions until a time delay of t_{PU} has elapsed after the moment that V_{CC} rises above the minimum V_{CC} threshold (see **Figure 66**). However, correct operation of the device is not guaranteed if V_{CC} returns below V_{CC} (min) during t_{PU} . No transaction should be sent to the device until the end of t_{PU} .

The device draws I_{POR} current during t_{PU} . After power up (t_{PU}) , the WRPGEN bit is reset and there is the option to be in the DPD mode or Standby mode. The DPDPOR bit in Configuration Register 4 (CFR4N[2]) controls if the device will be in DPD or Standby mode after the completion of POR (see **Table 52**). If the DPDPOR bit is enabled (CFR4N[2] = 1) the device is in DPD mode after power up. A Hardware reset (RESET# and DQ3_RESET#) required to return the device to Standby mode after POR.

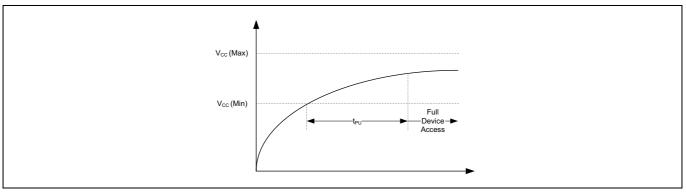

Figure 66 Power up

Quad SPI, 1.8V/3.0V

Features

4.14.2 Power down

During power down or voltage drops below $V_{CC}(\text{cut-off})$, the voltage must drop below $V_{CC}(\text{LOW})$ for a period of t_{PD} for the part to initialize correctly on power up (see **Figure 67**). If during a voltage drop the V_{CC} stays above $V_{CC}(\text{cut-off})$ the part will stay initialized and will work correctly when V_{CC} is again above $V_{CC}(\text{min})$. In the event POR did not complete correctly after power up, the assertion of the RESET# signal will restart the POR process.

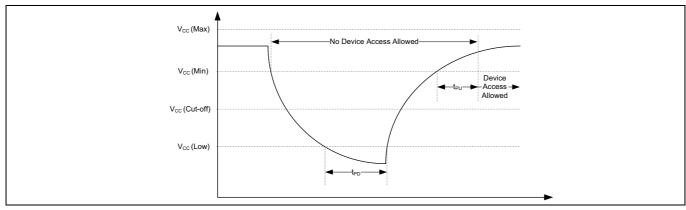

Figure 67 Power down and voltage drop

Registers

5 Registers

Registers are small groups of storage cells used to configure as well as report the status of the device operations. HL-T/HS-T family of devices use separate nonvolatile and volatile storage groups to implement the different register bit types for legacy compatibility as well as new functionality. Each register is organized as a group of volatile bits with associated nonvolatile bits (if permanence is required). During power-up, hardware reset or software reset, the data in the nonvolatile bits of the register is transferred to the volatile bits to provide the default state of the volatile bits. When writing new data to nonvolatile bits of the register, the volatile bits are also updated with the new data. However, when writing new data to the volatile register bits the nonvolatile bits retain the old data. The register structure is shown in **Figure 68**.

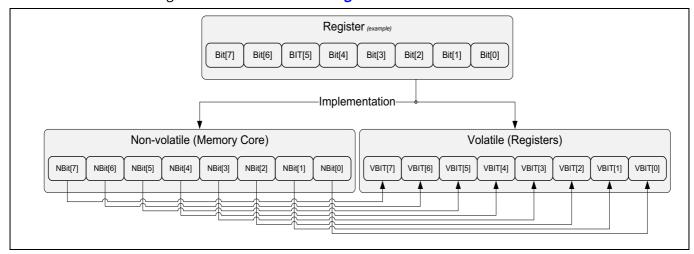

Figure 68 Register structure

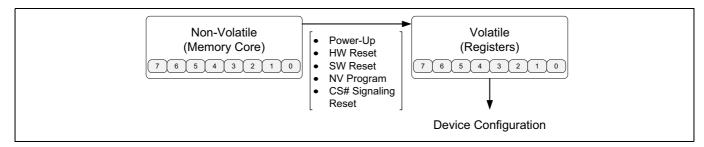

Figure 69 Data movement within register components

Quad SPI, 1.8V/3.0V

Registers

Register naming convention 5.1

Table 40 **Register bit description convention**

Bit Number	Name	Function	Read/Write	Factory default (binary)	Description	
REGNAME#T[x] T = N, V, O Descending Order	-	-	Possible Options: N/A - Not Applicable R - Readable Only R/W - Readable and Writable R/1 - Readable and One Time Program- mable	Possible Options: 0 1	Format: Description of the Configuration bit 0 = Option '0' selection of the Bit 1 = Option '1' selection of the Bit Dependency: Is this Bit part of a function which requires multiple bits for implementation?	

Status register 1 (STR1x) **5.2**

Status Register 1 contains both status and control bits. The functionality of supported Status Register 1 type is described in Table 41.

Status register 1^[22]

Table 41	Status register 1		Status register 1.		
Bit number	Name	Function	Read/Write N=Nonvolatile V=Volatile	Factory default (binary)	Description
STR1N[7] STR1V[7]	STCFWR	Status Register 1 and Configuration Register 1,2,3,4 Protection Selection against write (erase/program)	N->R/W V->R/W	0	Description: The STCFWR bit selects enabling and disabling writes (erase/program) to Status Register 1 and configuration registers 1, 2, 3, 4 based on WP# (Write Protect Pin) in Single SPI mode. When STCFWR bit is enabled with WP# LOW, any transaction that can change status or configuration registers is ignored, effectively locking the state of the device. If WP#/DQ[2] is HIGH (irrespective of STCFWR), Status and Configuration Registers can be changed. Selection Options: 1 = WP# based protection is enabled 0 = WP# based protection is disabled Dependency: N/A
STR1V[6]	PRGERR	Programming Error Status Flag	V -> R	0	Description: The PRGERR bit indicates program operation success or failure. When the PRGERR bit is set to a '1', it indicates that there was an error in the last programming operation. PRGERR bit is also set when a program operation is attempted within a protected memory region. When PRGERR is set, it can only be cleared with the Clear Program and Erase Failure Flags transaction or a hardware/software reset (see Table 42). Note The device will only go to standby mode once the PRGERR flag is cleared. Selection Options: 0 = Last programming operation was successful 1 = Last programming operation was unsuccessful Dependency: N/A
STR1V[5]	ERSERR	Erasing Error Status Flag	V -> R	0	Description: The ERSERR bit indicates erase operation success or failure. When the ERSERR bit is set to a '1', it indicates that there was an error in the last erasing operation. ERSERR bit is also set when a erase operation is attempted within a protected memory sector. When ERSERR is set, it can only be cleared with the Clear Program and Erase Failure Flags transaction or a hardware/software reset (see Table 43). Note The device will only go to standby mode once the ERSERR flag is cleared. Selection Options: 0 = Last erase operation was successful 1 = Last erase operation was unsuccessful Dependency: N/A

Note
22. STR1x value during POR, Hardware Reset, Software Reset, DPD Exit, and CS# Signaling Reset is not valid.

Quad SPI, 1.8V/3.0V

Registers

Status register 1^[22] (continued) Table 41

Bit number	Name	Function	Read/Write N=Nonvolatile V=Volatile	Factory default (binary)	Description
STR1N[4:2] STR1V[4:2]	LBPROT[2:0]	Legacy Block Protection based Memory Array size selection	If PLPROT = 0 N -> R/W V -> R/W If PLPROT = 1 N -> R V -> R	000	Description: The LBPROT[2:0] bits define the memory array size to be protected against program and erase transactions. Based on the LBPROT[2:0] configuration, either top 1/64, 1/4, 1/2, etc. or bottom 1/64, 1/4, 1/2, etc., or up to the entire array is protected. Note If PLPROT bit - Permanent Locking selection of Legacy Block Protection and 4KB Sector Architecture (CFR1x[4]) is set to a '1', the LBPROT[2:0] bits cannot be erased or programmed. Selection Options: 000 = Protection is disabled 001 = 1/64th of the (top/bottom) array protection is enabled 010 = 1/32nd of the (top/bottom) array protection is enabled 111 = All sectors are protected
					Dependency: TBPROT (CFR1x[5])
STR1V[1]	WRPGEN	Write/Program Enable Status Flag	V -> R	0	Description: The WRPGEN bit must be set to '1' to enable all program, erase or register write operations - it provides protection against inadvertent changes to memory or register values. The Write Enable and Write Enable Volatile transactions set the WRPGEN bit to '1' to allow program, erase or write transactions to execute. The Write Disable (WRDIS_0_0) transaction resets WRPGEN to a '0' to prevent all program, erase, and write transactions from execution. The WRPGEN bit is cleared to '0' at the end of any successful program, erase or register write operation. After a power down / power up sequence or a hardware/software reset, the Deep Power Down WRPGEN bit is cleared to '0'. Selection Options: 0 = Program, erase or register write is disabled 1 = Program, erase or register write is enabled Dependency: N/A
STR1V[0]	RDYBSY	Device Ready/Busy Status Flag	V -> R	0	Description: The RDYBSY bit indicates whether the device is performing an embedded operation or is in standby mode ready to receive new transactions. Note The PRGERR and ERSERR status bits are updated while RDYBSY is set. If PRGERR or ERSERR are set, the RDYBSY bit will remain set indicating the device is busy and unable to receive new transactions. A Clear Program and Erase Failure Flags transaction must be executed to return the device to standby mode. Selection Options: 0 = Device is in standby mode ready to receive new operation transactions 1 = Device is busy and unable to receive new operation transactions Dependency: N/A

Note
22. STR1x value during POR, Hardware Reset, Software Reset, DPD Exit, and CS# Signaling Reset is not valid.

Table 42 **PRGERR summary**

Error flag	Symbol	Conditions	
		Bits cannot be programmed '1' to '0'	
		Trying to program in a protected region

		SafeBoot Failure

5.3 Status register 2 (STR2x)

Status Register 2 provides device status on operations. The functionality of supported Status Register 2 type is described in **Table 44**.

Table 44 Status register 2^[23]

Bit number	Name	Function	Read/Write N = Nonvolatile V = Volatile	Factory default (binary)	Description
STR2V[7:5]	RESRVD	Reserved for future use	V -> R	0	This bit is Reserved for future use. This bit must always be written/loaded to its default state.
					Description: The DICRCS bit is used to determine when the device is in Memory Array Data Integrity Cyclic Redundancy Check suspend mode.
STR2V[4]	DICRCS	Memory Array Data Integrity Cyclic Redundancy Check Suspend Status Flag	V -> R	0	Selection Options: 0 = Memory Array Data Integrity Cyclic Redundancy Check is not in suspend mode 1 = Memory Array Data Integrity Cyclic Redundancy Check is in suspend mode
					Dependency: N/A
STR2V[3] DICRCA	DICRCA	Memory Array Data Integrity Cyclic Redundancy Check Abort Status Flag	V -> R	0	Description: The DICRCA bit indicates that the Memory Array Data Integrity Cyclic Redundancy Check calculation operation was aborted. The abort condition is based on ending address (ENDADD) and starting address (STRADD) relationship. If ENDADD < STRADD + 3, then DICRCA will be set and the device will return to the Standby state. DICRCA flag gets cleared at the next Data Integrity Cyclic Redundancy Check calculation operation when ENDADD ≥ STRADD + 3.
		ABORT Status Hug			Selection Options: 0 = Memory Array Data Integrity Cyclic Redundancy Check calculation Is not aborted 1 = Memory Array Data Integrity Cyclic Redundancy Check calculation is aborted
					Dependency: N/A
		Sector Erase Success/Failure Status Flag	V -> R	0	Description: The SESTAT bit indicates whether the erase operation on the sector completed successfully. Evaluate Erase Status transaction must be executed prior to reading SESTAT bit which specifies the sector address.
STR2V[2]	SESTAT				Selection Options: 1 = Addressed sector was erased successfully 0 = Addressed sector was not erased successfully
					Dependency: N/A
					Description: The ERASES bit is used to indicate if the Erase operation is suspended.
STR2V[1] ERAS	ERASES	Erase operation Suspend Status Flag	V -> R	0	Selection Options: 0 = Erase operation is not in suspend mode 1 = Erase operation is in suspend mode
					Dependency: N/A
					Description: The PROGMS bit is used to indicate if the Program operation is suspended.
STR2V[0]	PROGMS	Program operation Suspend Status Flag	V -> R	0	Selection Options: 0 = Program operation is not in suspend mode 1 = Program operation is in suspend mode
					Dependency: N/A

Note

^{23.}STR2x value during POR, Hardware Reset, Software Reset, DPD Exit, and CS# Signaling Reset is not valid. STR2x bits are valid only when STR1V[0] / RDYBSY = 0.

Registers

5.4 Configuration register 1 (CFR1x)

Configuration Register 1 controls interface and data protection functions.

Table 45 Configuration register 1

Bit number	Name	Function	Read/Write N = Nonvolatile V = Volatile	Factory default (binary)	Description	
CFR1N[7] CFR1V[7]	RESRVD	Reserved for future use	N -> R/W V -> R/W	0	This bit is Reserved for future use. This bit must always be written/loaded to its default state.	
CFR1N[6] CFR1V[6]	SP4KBS	Split 4KB Sectors selection between top and bottom address space	If PLPROT = 0 N -> R/W V -> R If PLPROT = 1 N -> R V -> R	0	Description: The SP4KBS bit selects whether the 4KB sectors are grouped together or evenly split between High and LOW address ranges (see Table 46). Selection Options: 0 = 4KB Sectors are grouped together 1 = 4KB Sectors are split between High and Low Addresses Dependency: TB4KBS(CFR1N[2])	
CFR1N[5] CFR1V[5]	TBPROT	Top or Bottom Protection selection for Legacy Protection Mode	If PLPROT = 0 N -> R/W V -> R If PLPROT = 1 N -> R V -> R	0	Description: The TBPROT bit selects the reference point of the Legacy Block Protection bits (LBPROT[2:0]) in the Status Register on whether the protection starts from the top or starts from the bottom of the address range. The bit also selects a memory address range (lowest or highest) to remain readable is available for reading during Read Password Protection mode even before a successful Password entry is completed (see Table 47). Selection Options: 0 = Legacy Protection is applicable in the top half of the address range 1 = Legacy Protection is applicable in the bottom half of the address range Dependency: LBPROT[2:0] (STR1x[3:1])	
CFR1N[4] CFR1V[4]	PLPROT	Permanent Locking selection of Legacy Block Protection and 4KB Sector Architecture	N -> R/1 V -> R	0	Description: The PLPROT bit permanently protects the Legacy Block Protection and 4KB Sector location. It thereby permanently protects the memory array protection scheme and sector architecture (see Table 47). Note PLPROT protects LBPROT[2:0], SP4KBS, TBPROT, and TB4KBS bits from program and erase. It is recommended to configure these bits before configuring the PLPROT bit. Selection Options: 0 = Legacy Block Protection and 4KB Sector Location are not protected 1 = Legacy Block Protection and 4KB Sector Location are protected Dependency: N/A	
CFR1N[3] CFR1V[3]	RESRVD	Reserved for future use	N -> R/W V -> R/W	0	This bit is Reserved for future use. This bit must always be written/loaded to its default state.	
CFR1N[2] CFR1V[2]	TB4KBS	Top or Bottom Address Range selection for 4KB Sector Block	If PLPROT = 0 N -> R/W V -> R If PLPROT = 1 N -> R V -> R	0	Description: The TB4KBS bit defines the logical address location of the 4KB sector block. The 4KB sector block replaces the fitting portion of the highest or lowest address sector (see Table 46). Selection Options: 0 = 4KB Sector Block is in the bottom of the memory address space 1 = 4KB Sector Block is in the top of the memory address space Dependency: SP4KBS (CFR1x[6])	

Quad SPI, 1.8V/3.0V

Registers

15	166	166	166	166	166	102

- 24. When using the ECC error reporting mechanisms, the read output data must be at least 2 bytes for correct ECC reporting.
- 24. When using the ECC error reporting mechanisms, the read output data must be at least 2 bytes for correct ECC reporting.

 25. CK frequency > 166MHz SDR, or > 102MHz DDR is not supported by this family of devices.

 26. The Fast Read 4-byte address, QPI, Dual I/O, Quad I/O, QPI, DDR Quad I/O, and DDR QPI, protocols include Continuous Read Mode bits following the address. The clock cycles for these bits are not counted as part of the latency cycles shown in the table. For example, the legacy Quad I/O transaction has two Continuous Read mode cycles following the address. Therefore, the legacy Quad I/O transaction without additional read latency is supported only up to the frequency shown in the table for a read latency of 0 cycles. By increasing the variable read latency, the frequency of the Quad I/O transaction can be increased to allow operation up to the maximum supported 166MHz frequency.
- 27. Read Any Register transaction uses these latency cycles for reading nonvolatile registers.
 28. Read SFDP transaction always have a dummy cycle of 8 and the maximum frequencies for different interfaces related to eight dummy cycles. Read Unique ID has 32 cycles of latency.
 29. Secure Silicon Read (4-4-4) latency cycle > 0.

Quad SPI, 1.8V/3.0V

Registers

5.6 Configuration register 3 (CFR3x)

Configuration register 3 controls transaction behavior.

Table 50 Configuration register 3

Bit number	Name	Function	Read/Write N = Nonvolatile	Factory default	Description
CFR3N[7:6] CFR3V[7:6]	VRGLAT[1:0]	Volatile Register Read Latency selection - Dummy cycles required for initial data access	V = Volatile N -> R/W V -> R/W	(binary)	Description: The VRGLAT[1:0] bits control the read latency (dummy cycles) delay in all variable latency register read transactions. VRGLAT[1:0] selection allows the user to adjust the read latency during normal operation based on different operating frequencies (see Table 51). Selection Options: 00, 01, 10, 11 Latency Cycles Selection based on transaction opcodes
					Dependency: N/A
CFR3N[5] CFR3V[5]	ВЬКСНК	Blank Check selection during Erase operation for better endurance	N -> R/W V -> R/W	0	Description: When this feature is enabled an erase transaction first evaluates the erase status of the sector. If the sector is found to erased, the erase operation is aborted. In other words, the erase operation is only executed if programmed bits are found in the sector. Disabling BLKCHK executes an erase operation unconditionally. Selection Options:
		Tor better endurance			0 = Blank Check is disabled before executing an erase operation 1 = Blank Check evaluation is enabled before executing an erase operation
					Dependency: N/A
CFR3N[4]	PGMBUF	Program Buffer Size selection	N -> R/W V -> R/W	0	Description: The PGMBUF bit selects the Programming Buffer size which is used for page programming. Program buffer size affects the device programming time. Note If programming data exceeds the program buffer size, data gets wrapped.
CFR3V[4]	PGMBUF			O	Selection Options: 0 = 256 Byte Write Buffer Size 1 = 512 Byte Write Buffer Size
					Dependency: N/A
CFR3N[3] CFR3V[3]	UNHYSA	Uniform or Hybrid Sector Architecture selection	N -> R/W V -> R	0	Description: The UNHYSA bit selects between uniform (all 256KB sectors) or hybrid (4KB sectors and 256KB sectors) sector architecture. If hybrid sector architecture is selected, 4KB sector block is made part of the main flash array address map. The 4KB sector block can overlay at either the highest or the lowest address range of the device. If uniform sector architecture is selected, 4KB sector block is removed from the address map and all sectors are of uniform size. Note Hybrid sector architecture also enables 4KB Sector Erase transaction (20h). Otherwise, 4KB Sector Erase transaction, if issued, is ignored by the device.
					Selection Options: 0 = Hybrid Sector Architecture (combination of 4KB sectors and 256KB sectors) 1 = Uniform Sector Architecture (all 256KB sectors)
					Dependency: SP4KBS(CFR1N[6]), TB4KBS(CFR1N[2])
CFR3N[2] CFR3V[2]	CLSRSM	Clear Status or Resume transaction 30h selection	N -> R/W V -> R/W	0	Description: The CLSRSM bit selects how the 30h transaction is used in the device. CLRRSM controls whether 30h transaction is used as clear status transaction or as an alternate Program / Erase / Data Integrity Check resume transaction. Selection Options: 0 = Clear Status Register transaction 1 = Program / Erase / Data Integrity Check Resume transaction Dependency: N/A
CFR3N[1] CFR3V[1]	RESRVD	Reserved for future use	N -> R/W V -> R/W	0	This bit is Reserved for future use. This bit must always be written/loaded to its default state.
CFR3N[0] CFR3V[0]	LSFRST	Legacy Software Reset transaction F0h selection	N -> R/W V -> R/W	0	Description: The LSFRST bit selects the software reset transaction. It allows the legacy F0h single transaction for software reset. Selection Options: 0 = Legacy Software Reset is disabled 1 = Legacy Software Reset is enabled Dependency: N/A

Quad SPI, 1.8V/3.0V

Configuration register 4 (CFR4x) 5.7

Configuration Register 4 controls the main flash array read transactions burst wrap behavior and output driver impedance.

Table 52 **Configuration register 4**

Bit number	Name	Function	Read/Write N = Nonvolatile V = Volatile	Factory default (binary)	Description
					Description: The IOIMPD[2:0] bits select the IO driver output impedance (drive strength). The output impedance configuration bits adjust the drive strength during normal device operation to meet system signal integrity requirements.
CFR4N[7:5] CFR4V[7:5]	IOIMPD[2:0]	I/O Driver Output Impedance selection	N -> R/W V -> R/W	000	Selection Options: $000 = 45\Omega \text{ (Factory Default)} \\ 001 = 120\Omega \\ 010 = 90\Omega \\ 011 = 60\Omega \\ 100 = 45\Omega \\ 101 = 30\Omega \\ 111 = 20\Omega \\ 111 = 15\Omega$
					Dependency: N/A
CFR4N[4] CFR4V[4]	RBSTWP	Read Burst Wrap Enable selection	N -> R/W V -> R/W	0	Description: The RBSTWP bit selects the read burst wrap feature. It allows the device to enter and exit burst wrapped read mode during normal operation. The wrap length is selected by RBSTWL[1:0] bits. Selection Options: 0 = Read Wrapped Burst disabled 1 = Read Wrapped Burst enabled Dependency: RBSTWL[1:0] (CFR4x[1:0])
CFR4N[3] CFR4V[3]	ECC12S	Error Correction Code (ECC) 1-bit or 1-bit/2-bit error correction selection	N -> R/W V -> R/W	1	Description: The ECC12S bit selects between 1-bit ECC error detection/correction or both 1-bit ECC error detection and correction and 2-bit ECC error detection. This configuration option affects Address Trap Register and ECC Counter Register functionalities as well. The host needs to erase and reprogram the data in the SEMPER™ Flash memory upon ECC configuration change (1-bit correction to 1-bit correction and 2-bit detection or vice versa). Selection Options: 0 = 1-bit ECC Error Detection/Correction 1 = 1-bit ECC Error Detection/Correction and 2-bit ECC error detection Dependency: N/A

Notes
30. CK frequency > 166MHz SDR, or 102MHz DDR is not supported by this family of devices.
31. Read Any Register transaction uses these latency cycles for reading volatile registers.
32. Read SFDP transaction always have a dummy cycle of 8 and the maximum frequencies for different interfaces related to eight dummy cycles. Read Unique ID has 32 cycles of latency.

Quad SPI, 1.8V/3.0V

Registers

 Table 52
 Configuration register 4 (continued)

Bit number	Name	Function	Read/Write N = Nonvolatile V = Volatile	Factory default (binary)	Description
CFR4N[2] CFR4V[2]	DPDPOR	Deep Power Down power saving mode entry selection upon POR	N -> R/W V -> R	0	Description: The DPDPOR bit selects if the device will be in either Deep Power Down (DPD) mode or the Standby mode after the completion of POR. If enabled, DPDPOR configures the device to start in DPD mode to reduce current consumption until the device is needed. If the device is in DPD, a pulse on CS# or a Hardware reset will return the device to Standby mode. Selection Options: 0 = Standby mode is entered upon the completion of POR 1 = Deep Power Down Power mode is entered upon the completion of POR Dependency: N/A
CFR4N[1:0] CFR4V[1:0]	RBSTWL[1:0	Read Burst Wrap Length selection	N -> R/W V -> R/W	00	Description: The RBSTWL[1:0] bits select the read burst wrap length and alignment during normal operation. It selects the fixed length/aligned group of 8-, 16-, 32-, or 64-bytes (see Table 53). Selection Options: 00 = 8 Bytes Wrap length 01 = 16 Bytes Wrap length 10 = 32 Bytes Wrap length 11 = 64 Bytes Wrap length Dependency: RBSTWP (CFR4x[4])

5.8 Memory array data integrity check CRC register (DCRV)

The memory array Data Integrity Check CRC Register (DCRV) stores the results of the CRC calculation on the data contained between the specified starting and ending addresses.

Table 54 Memory array data integrity check CRC register

Bit number	Name	Function	Read/Write N=Nonvolatile V=Volatile	Factory default (hex)	Description
DCRV[31:0]	DTCRCV[31:0]	Memory Array Data CRC Checksum Value	V -> R	0x00000000	Description: The DTCRCV[31:0 bits store the checksum value of the CRC process on the memory array data contained within the starting address and the ending address. Selection Options: Checksum Value Dependency: N/A

Quad SPI, 1.8V/3.0V

Registers

ECC status register (ECSV) 5.9

The ECC Status Register (ECSV) contains the ECC status of any error correction action performed on the unit data whose byte was addressed during last read.

Note Unit data is defined as the number of bytes over which the ECC is calculated. HL-T/HS-T family devices have a 16 bytes (128 bits) unit data.

Table 55 **ECC** status register

Bit number	Name	Function	Read/Write N=Nonvolatile V=Volatile	Factory default (binary)	Description
ECSV[7:5]	RESRVD	Reserved for future use	V -> R	000	This bit is Reserved for future use. This bit must always be written/loaded to its default state.
ECSV[4] ECC2BT	ECC2BT	ECC Error 2-bit Error Detection Flag	V -> R	0	Description: The ECC2BT bit indicates that a 2-bit ECC Error was detected in the data unit (16 bytes). A Clear ECC Status Register transaction (CLECC_0_0) will reset ECC2BT. Note ECC2BT is updated every time any memory address is read and is sticky, i.e. once it is set, it remains set. The ECC2BT status is maintained until a Clear ECC Status Register transaction (CLECC_0_0) is executed. Note ECC1BT is not valid if ECC2BT status flag is set.
					Selection Options: 0 = No 2-Bit ECC Error was detected in the data unit (16 bytes) 1 = 2-bit ECC Error was detected in the data unit (16 bytes) Dependency: CFR4x[3]
ECSV[3]	ECC1BT	ECC Error 1-bit Error Detection and	V -> R	0	Description: The ECC1BT bit indicates that a 1-bit ECC Error was detected and corrected in the data unit (16 bytes). A Clear ECC Status Register transaction (CLECC_0_0) will reset ECC1BT. Note ECC1BT is updated every time any memory address is read and is sticky, i.e. once it is set, it remains set. The ECC1BT status is maintained until a Clear ECC Status Register transaction (CLECC_0_0) is executed.
		Correction Flag			Selection Options: 0 = No 1-Bit ECC Error was detected in the data unit (16 bytes) 1 = 1-bit ECC Error was detected in the data unit (16 bytes) Dependency: N/A
ECSV[2:0]	RESRVD	Reserved for future use	V -> R	000	This bit is Reserved for future use. This bit must always be written/loaded to its default state.

ECC address trap register (EATV) 5.10

The ECC Address Trap Register (EATV) stores the address of the ECC unit data where either a 1-Bit/2-Bit error or only a 1-Bit error occurred during a read operation. It stores the ECC unit address of the first ECC error captured during a memory read operation since the last Clear ECC transaction.

Table 56 **ECC** address trap register

Bit number	Name	Function	Read/Write N = Nonvolatile V = Volatile	Factory default (hex)	Description
EATV[31:0]	ECCATP[31:0]	ECC 1-bit and 2-bit Error Address Trap Register	V -> R	0x00000000	Description: The Address Trap Register (ECCATP[31:0]) stores the ECC unit data address where a 1-Bit/2-Bit error occurred during a read operation. ECCATP[31:0] stores the ECC unit address of the first ECC error captured during a memory read operation since the last Clear ECC Status Register transaction (CLECC_0_0). Note ECCATP[31:0] is only updated during Read Instruction. Note Mask non-valid upper ECCATP address bits from ECC unit address. Note Clear ECC Status Register transaction (CLECC_0_0), POR or Hardware/Software reset clears the EATV[31:0] to 0x00000000. Selection Options: ECC Error Data Unit Address Dependency: N/A

Quad SPI, 1.8V/3.0V

Registers

ECC error detection count register (ECTV) 5.11

The ECC Error Detection Counter Register (ECTV) stores the number of either 1-Bit/2-Bit or only 1-Bit ECC errors have occurred during read operations since the last POR or hardware/software reset.

Table 57 **ECC** count register

Bit number	Name	Function	Read/Write N = Nonvolatile V = Volatile	Factory default (hex)	Description
ECTV[15:0]	ECCCNT[15:0]	ECC 1-bit and 2-bit Error Count Register	V -> R	0x0000	Description: The ECCCNT[15:0] stores the number of 1-bit/2-bit ECC errors occurred during read operations since the last POR or hardware/software reset. Note ECCCNT[15:0] is only updated during Read Instruction. Note Only one ECC error is counted for each data unit. If multiple read transactions access the same unit data containing an ECC error, the ECCCNT[15:0] will increment each time the unit data is read. Note Once the count reaches 0xFFFF, the ECCCNT[15:0] will stop incrementing Note POR or Hardware/Software reset clears the ECCNT[15:0] to 0x0000. Selection Options: ECC Error Count Dependency: N/A

Advanced sector protection register (ASPO) 5.12

The ASP Register (ASPO) configures the behavior of Advanced Sector Protection scheme.

Table 58 **Advanced sector protection register**

Bit number	Name	Function	Read/Write N = Nonvolatile V = Volatile	Factory default (binary)	Description
ASPO[15:6]	RESRVD	Reserved for future use	N -> R/1	1111111111	This bit is Reserved for future use. This bit must always be written/loaded to its default state.
ASPO[5]	ASPRDP	Read Password Based Protection Selection	N -> R/1	1	Description: The ASPRDP bit selects the Read Password Mode Protection mode. Read Password Protection mode works in conjunction with Password Protection mode to protect all sectors from Read/Erase/Program. Based on TBPROT configuration bit (CFR1x[5]), either the top or bottom sector is available for reading. Selection Options: 0 = Read Password Protection Mode is enabled 1 = Read Password Protection Mode is disabled Dependency: TBPROT (CFR1x[5])
ASPO[4]	ASPDYB	Dynamic Protection (DYB) for all sectors at power-up Selection	N -> R/1	1	Description: The ASPDYB bit selects whether all DYB bits (sectors) are in the protected state following power-up or hardware reset. DYB bits will individually need to be reset to change sector protections. Selection Options: 0 = DYB based sector protection enabled at power-up or hardware reset 1 = DYB based sector protection disabled at power-up or hardware reset Dependency: N/A
ASPO[3]	ASPPPB	Permanent Protection (PPB) bits for all sectors programma- bility Selection	N -> R/1	1	Description: The ASPPPB bit selects whether all PPB bits are OTP making PPB sector protection permanent. Note ASPPPB disables PPB erase transaction (ERPPB_0_0). Selection Options: 0 = PPB bits are OTP 1 = PPB bits can be erased and programmed as desired Dependency: N/A

Quad SPI, 1.8V/3.0V

Registers

Advanced sector protection register (continued) Table 58

Table 30		inced sector prote		(continuou)	
Bit number	Name	Function	Read/Write N = Nonvolatile V = Volatile	Factory default (binary)	Description
ASPO[2]	ASPPWD	Password Based Protection Selection	N -> R/1	1	Description: The ASPPWD bit selects the Password Protection Mode. Password Protection mode protects all PPB bits till the correct password is entered. The ASPPWD can also be used in combination with the ASPRDP to protect all registers and all memory from erase/program and to protect sectors from being read as well till the correct password is provided - except for top or bottom sector which is available for reading based on TBPROT configuration bit (CFR1x[5]). Note When ASPPWD is selected, ASPO[15:0], CFR1N[7:2] and PWDO[63:0] are protected against Write operations. Selection Options: 0 = Password Protection Mode is enabled 1 = Password Protection Mode is disabled
					Dependency: N/A
ASPO[1]	ASPPER	Persistent Protection Selection (Register Protection Selection)	N -> R/1	1	Description: The ASPPER bit selects the Persistent Protection Mode. The Persistent Protection mode (ASPPER) protects the ASPO[15:0], CFR1x[6, 5, 4, 2] and CFR3x[3] registers from erase or program. Selection Options: 0 = Persistent Protection Mode is enabled 1 = Persistent Protection Mode is disabled Dependency: N/A
ASPO[0]	ASPPRM	Permanent Protection Selection	N -> R/1	1	Description: The ASPPRM bit selects the Permanent Protection Mode. The Permanent Protection mode (ASPPRM) permanently protects the PPB bits from erase or program. ASPPRM bit should be programmed once all the PPB based sector protections are finalized. Note Permanent protection is independent of the PPBLOCK bit. Selection Options: 0 = Permanent Protection Mode is enabled 1 = Permanent Protection Mode is disabled Dependency: N/A

ASP password register (PWDO) 5.13

The ASP Password Register (PWDO) is used to permanently define a password.

Table 59 **Password register**

Bit number	Name	Function	Read/Write N = Nonvolatile V = Volatile	Factory default (hex)	Description
PWDO[63:0]	PASWRD[63:0]	Password Register	N -> R/1	0xFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFF	Description: The PASWRD[63:0] permanently stores a password used in password protected modes of operation. When the Password Protection Mode is enabled, this register will output the undefined data upon read password request. Selection Options: Password Dependency: N/A

Quad SPI, 1.8V/3.0V

Registers

ASP PPB lock register (PPLV) 5.14

The PPBLCK bit in the ASP PPB Lock Register (PPLV) is used to protect the PPB bits.

ASP PPB lock register Table 60

Bit number	Name	Function	Read/Write N = Nonvolatile V = Volatile	Factory default (binary)	Description
PPLV[7:1]	RESVRD	Reserved for future use	V -> R	0000000	This bit is Reserved for future use. This bit must always be written/loaded to its default state.
PPLV[0]	PPBLCK	PPB Temporary Protection Selection	V -> R/W	1, ASPO[2:1]	Description: The PPBLCK bit is used to temporarily protect all the PPB bits. Selection Options: 1 = PPB Bits can be erased or programmed 0 = PPB bits are protected against erase or program till the next POR or hardware reset Dependency: N/A

ASP PPB access register (PPAV) 5.15

The ASP PPB Access Register (PPAV) is used to provide the state of each sector's PPB protection bit.

ASP PPB access register

Bit number	Name	Function	Read/Write N = Nonvolatile V = Volatile	Factory Default (binary)	Description
PPAV[7:0]	PPBACS[7:0]	Sector Based PPB Protection Status	N -> R/W	11111111	Description: The PPBACS[7:0] bits are used to provide the state of the individual sector's PPB bit. Selection Options: FF = PPB for the sector addressed by the Read PPB transaction (RDPPB_4_0) is 1, not protecting that sector from program or erase operations 00 = PPB for the sector addressed by the Read PPB transaction (RDPPB_4_0) is 0, protecting that sector from program or erase operations Dependency: N/A

ASP dynamic block access register (DYAV) 5.16

The ASP DYB Access Register (DYAV) is used to provide the state of each sector's DYB protection bit.

ASP DYB access register Table 62

Bit number	Name	Function	Read/Write N = Nonvolatile V = Volatile	Factory default (binary)	Description			
DYAV[7:0]	DYBACS[7:0]	Sector Based DYB Protection Status	V -> R/W	11111111	Description: The DYBACS[7:0] bits are used to provide the state of the individual sector's DYB bit. Selection Options: FF = DYB for the sector addressed by the Read DYB transaction (RDDYB_4_0) is 1, not protecting that sector from program or erase operations 00 = DYB for the sector addressed by the Read DYB transaction (RDDYB_4_0) is 0, protecting that sector from program or erase operations Dependency: N/A

Registers

5.17 Data learning register (DLPx)

The Data Learning Pattern Register (DLPx) contains the 8-bit Data Learning pattern.

Table 63 Data learning register

Bit number	Name	Function	Read/Write N = Nonvolatile V = Volatile	Factory default (hex)	Description
DLPN[7:0] DLPV[7:0]	DTLRPT[7:0]	Data Learning Pattern Selection	N -> R/W V -> R/W	0x00	Description: The DTLRPT[7:0] bits provide the data pattern which is output during Read Latency cycles. This pattern is transferred to the host during SDR/DDR read transaction latency cycles to provide a training pattern to help the host more accurately center the data capture point in the received data bits. Selection Options: Pattern Dependency: N/A

Table 64 DLR feature summary

Interface Type	SDR	DDR
1-1-1	N/A	N/A
1-2-2		
1-1-4	Yes	
1-4-4		Yes
4-4-4		
AutoBoot	N/A	N/A
Register Access		

Table 65 Data learning pattern behavior

Interface data type	Latency type 1	Latency type 2
SDR	Greater than or equal to 9; DLP on last 8 Clock Cycles	Less than 9; DLP is truncated
DDR	Greater than or equal to 5; DLP on last 4 Clock Cycles	Less than 5; DLP is truncated

5.18 AutoBoot register (ATBN)

The AutoBoot Register (ATBN) provides a means to automatically read boot code as part of the power-on reset, or hardware reset process.

Table 66 AutoBoot Register

Bit number	Name	Function	Read/Write N = Nonvolatile V = Volatile	Factory Default (binary)	Description
ATBN[31:9]	STADR[22:0]	Starting Address Selection where AutoBoot will start reading data from	N -> R/W	000000000000000000000000000000000000000	Description: The STADR[22:0] bits set the starting address from which the device will output the read data. Selection Options: Address Bits Dependency: N/A
ATBN[8:1]	STDLY[7:0]	AutoBoot Read Starting Delay Selection	N -> R/W	00000000	Description: The STDLY[7:0] bits specify the initial delay (clock cycles) needed by the host before it can accept data. Note STDLY[7:0]=0x00 is valid up to 50MHz. STDLY[7:0] > 0x00 or higher is valid up to 166MHz. Selection Options: Address Bits Dependency: N/A
ATBN[0]	ATBTEN	AutoBoot Feature Selection	N -> R/W	0	Description: The ATBTEN bit enables or disables the AutoBoot feature. Selection Options: 0 = AutoBoot feature disabled 1 = AutoBoot feature enabled Dependency: N/A

Quad SPI, 1.8V/3.0V

Registers

Sector Erase Count Register (SECV) 5.19

The Sector Erase Count Register (SECV) contains the number of times the addressed sector has been erased.

Sector Erase Count Register Table 67

Bit number	Name	Function	Read/Write N = Nonvolatile V = Volatile	Factory default (hex)	Description
SECV[23]	SECCPT	Sector Erase Count Corruption Status Flag	V-> R	0x0	Description: The SECCPT bit is used to determine if the reported sector erase count is corrupted and was reset. Note If SECCPT is set due to count corruption, it will reset to 0 on the next successful erase operation on the selected sector. Selection Options: 0 = Sector Erase Count is not corrupted and is valid 1 = Sector Erase Count is corrupted and is not valid Dependency: N/A
SECV[22:0]	SECVAL[22:0]	Sector Erase Count Value	V -> R	0x000000	Description: The SECVAL[22:0] bits store the number of times a sector has been erased. Selection Options: Value Dependency: N/A

Infineon® Endurance Flex architecture selection register (EFXx) 5.20

The Infineon® Endurance Flex architecture selection registers (EFXx) define the long retention / high endurance regions based on a four pointer based architecture.

Infineon® Endurance Flex architecture selection register (pointer 4) Table 68

Bit number	Name	Function	Read/Write N = Nonvolatile V = Volatile	Factory default (binary)	Description
EFX4O[10:2]	EPTAD4[8:0]	Infineon® Endurance Flex architecture Pointer 4 Address Selection	N -> R/1	111111111	Description: The EPTAD4[8:0] bits define the 9-bit address of the beginning sector from where the long retention / high endurance region is defined. Selection Options: Pointer Address Dependency: N/A
EFX4O[1]	ERGNT4	Infineon® Endurance Flex architecture Pointer 4 based Region Type Selection	N -> R/1	1	Description: The ERGNT4 bit defines whether the region is long retention or high endurance. Selection Options: 0 = Long Retention Sectors 1 = High Endurance Sectors Dependency: N/A
EFX4O[0]	EPTEB4	Infineon® Endurance Flex architecture Pointer 4 Enable# Selection	N -> R/1	1	Description: The EPTEN4 bit define whether the wear leveling pointer is enabled/disabled. Selection Options: 0 = Pointer Address Enabled 1 = Pointer Address Disabled Dependency: N/A

Quad SPI, 1.8V/3.0V

Registers

Table 69 Infineon® Endurance Flex architecture selection register (pointer 3)

Bit number	Name	Function	Read/Write N = Nonvolatile V = Volatile	Factory default (binary)	Description	
EFX3O[10:2]	EPTAD3[8:0]	Infineon® Endurance Flex architecture Pointer 3 Address Selection	N -> R/1	111111111	Description: The EPTAD3[8:0] bits define the 9-bit address of the beginning sector from where the long retention / high endurance region is defined. Selection Options: Pointer Address Dependency: N/A	
EFX3O[1]	ERGNT3	Infineon® Endurance Flex architecture Pointer 3 based Region Type Selection	N -> R/1	1	Description: The ERGNT3 bit defines whether the region is long retention or high endurance. Selection Options: 0 = Long Retention Sectors 1 = High Endurance Sectors Dependency: N/A	
EFX3O[0]	ЕРТЕВЗ	Infineon® Endurance Flex architecture Pointer 3 Enable# Selection	N -> R/1	1	Description: The EPTEN3 bit define whether the wear leveling pointer is enabled/disabled. Selection Options: 0 = Pointer Address Enabled 1 = Pointer Address Disabled Dependency: N/A	

Table 70 Infineon® Endurance Flex architecture selection register (pointer 2)

Bit number	Name	Function	Read/Write N=Nonvolatile V=Volatile	Factory default (binary)	Description
EFX2O[10:2]	EPTAD2[8:0]	Infineon® Endurance Flex architecture Pointer 2 Address Selection	N -> R/1	111111111	Description: The EPTAD2[8:0] bits define the 9-bit address of the beginning sector from where the long retention / high endurance region is defined. Selection Options: Pointer Address Dependency: N/A
EFX2O[1]	ERGNT2	Infineon® Endurance Flex architecture Pointer 2 based Region Type Selection	N -> R/1	1	Description: The ERGNT2 bit defines whether the region is long retention or high endurance. Selection Options: 0 = Long Retention Sectors 1 = High Endurance Sectors Dependency: N/A
EFX2O[0]	EPTEB2	Infineon® Endurance Flex architecture Pointer 2 Enable# Selection	N -> R/1	1	Description: EPTEN2 bit define whether the wear leveling pointer is enabled/disabled. Selection Options: 0 = Pointer Address Enabled 1 = Pointer Address Disabled Dependency: N/A

Registers

Table 71 Infineon® Endurance Flex architecture selection register (pointer 1)

Bit number	Name	Function	Read/Write N = Nonvolatile V = Volatile	Factory default (binary)	Description
EFX10[10:2]	EPTAD1[8:0]	Infineon® Endurance Flex architecture Pointer 1 Address Selection	N -> R/1	111111111	Description: The EPTAD1[8:0] bits define the 9-bit address of the beginning sector from where the long retention / high endurance region is defined. Selection Options: Pointer Address Dependency: N/A
EFX10[1]	ERGNT1	Infineon® Endurance Flex architecture Pointer 1 based Region Type Selection	N -> R/1	1	Description: The ERGNT1 bit defines whether the region is long retention or high endurance. Selection Options: 0 = Long Retention Sectors 1 = High Endurance Sectors Dependency: N/A
EFX1O[0]	EPTEB1	Infineon® Endurance Flex architecture Pointer 1 Enable# Selection	N -> R/1	1	Description: The EPTEN1 bit define whether the wear leveling pointer is enabled/disabled. Selection Options: 0 = Pointer Address Enabled 1 = Pointer Address Disabled Dependency: N/A

Table 72 Infineon® Endurance Flex architecture selection register (pointer 0)

Bit number	Name	Function	Read/Write N=Nonvolatile V=Volatile	Factory default (binary)	Description
EFX0O[1]	GBLSEL	All Sectors based Region type Selection	N -> R/1	1	Description: The GBLSEL bit defines whether all sectors are defined as long retention region or high endurance region. Note If all other pointer registers are disabled, this bit defines the behavior of the entire memory space and is hardwired to start at Sector 0. Selection Options: 0 = Long Retention Sectors 1 = High Endurance Sectors Dependency: N/A
EFX0O[0]	WRLVEN	Wear Leveling Enable Selection	N -> R/1	1	Description: The WRLVEN bit enables/disables the wear leveling feature. Selection Options: 0 = Wear Leveling Disabled 1 = Wear Leveling Enabled Dependency: N/A

6 Transaction table

6.1 1-1-1 transaction table

Table 73 1-1-1 transaction table

Function	Transaction name	Description	Prerequisite transaction	Byte 1 (Hex)	Byte 2 (Hex)	Byte 3 (Hex)	Byte 4 (Hex)	Byte 5 (Hex)	Byte 6 (Hex)	Byte 7 (Hex)	Byte 8 (Hex)	Byte 9 (Hex)	Transaction format	Max freq. (MHz)	Address length
	RDIDN_0_0	Read manufacturer and device identification transaction provides read access to manufacturer and device identification.	-	9F (CMD)	-	-	-	-	-	-	-	-	Figure 12	166	N/A
Read Device ID	RSFDP_3_0	Read JEDEC Serial Flash Discoverable Parameters transaction sequentially accesses the Serial Flash Discovery Parameters (SFDP).	-	5A (CMD)	ADDR [23:16]	ADDR [15:8]	ADDR [7:0]	-	-	-	-	-	Figure 13	50	3
	RDUID_0_0	Read Unique ID accesses a factory programmed 64-bit number which is unique to each device.	-	4C (CMD)	-	-	-	-	-	-	-	-			
	RDSR1_0_0	Read Status Register 1 transaction allows the Status Register 1 contents to be read from DQ1/SO.	-	05 (CMD)	-	-	-	-	-	-	-	-			
	RDSR2_0_0	Read Status Register-2 transaction allows the Status Register-2 contents to be read from DQ1/SO.	-	07 (CMD)	-	-	-	-	-	-	-	-	Figure 12		N/A
	RDCR1_0_0	Read Configuration Register-1 transaction allows the Configuration Register-1 contents to be read from DQ1/SO.	-	35 (CMD)	-	-	-	-	-	-	-	-			
	RDARG_C_0	Read Any Register transaction provides a way to read all addressed	-	65	ADDR [23:16]	ADDR [15:8]	ADDR [7:0]	-	-	-	-	-	Figure 13		3
	RDARG_C_0	nonvolatile and volatile device registers.	-	(CMD)	ADDR [31:24]	ADDR [23:16]	ADDR [15:8]	ADDR [7:0]	-	-	-	-	Figure 13	166	4
Register Access	WRENB_0_0	Write Enable sets the Write Enable Latch bit of the Status Register 1 to 1 to enable write, program, and erase transactions.	-	06 (CMD)	-	-	-	-	-	-	-	-			
	WRENV_0_0	Write Enable Volatile enable write of volatile Registers.	-	50 (CMD)	-	-	-	-	-	-	-	-	Figure 7		
	WRDIS_0_0	Write Disable sets the Write Enable Latch bit of the Status Register 1 to 0 to disable write, program, and erase transactions executaion.	-	04 (CMD)	-	-	-	-	-	-	-	-			N/A
	WRREG_0_1	Write Register transaction provides a way to write Status Register 1 and Configuration Registers 1 - 4	WRENB_0_0	01 (CMD)	Input STR1 data [7:0]	Input CFR1 data [7:0]	Input CFR2 data [7:0]	Input CFR3 data [7:0]	Input CFR4 data [7:0]	-	-	-	Figure 45		
	WRRSB_0_1	SafeBoot Write Register transaction to recover the device from configuration corruption.	WRENB_0_0	01 (CMD)	Input STR1 data [7:0]	Input CFR1 data [7:0]	Input CFR2 data [7:0]	Input CFR3 data [7:0]	Input CFR4 data [7:0]	Input 0x00	-	-	Figure 11		

Function	Transaction name	Description	Prerequisite transaction	Byte 1 (Hex)	Byte 2 (Hex)	Byte 3 (Hex)	Byte 4 (Hex)	Byte 5 (Hex)	Byte 6 (Hex)	Byte 7 (Hex)	Byte 8 (Hex)	Byte 9 (Hex)	Transaction format	Max freq. (MHz)	Address length
	WRARG C 1	Write Any Register transaction provides a way to write all addressed	WRENB 0 0	71	ADDR [23:16]	ADDR [15:8]	ADDR [7:0]	Input Data [7:0]	-	-	-	=	Figure 10		3
	WRARG_C_1	nonvolatile and volatile device registers.	WKENB_0_0	(CMD)	ADDR [31:24]	ADDR [23:16]	ADDR [15:8]	ADDR [7:0]	Input Data [7:0]	ı	-	ı	rigule 10		4
		Clear Program and Erase Failure Flags transaction resets STR1V[5] (Erase failure flag) and STR1V[6]	-	30 (CMD)	-	-	-	-	-	-	-	-			
	CLPEF_0_0	(Program failure flag)													
Register Access	CLI LI _U_U	Note This command may be disabled and the instruction value instead used for a program / erase resume command. See Configuration register 3 (CFR3x) on page 80.	1	82 (CMD)	-	-	-	-	-	1	-	-	Figure 7		
	EN4BA_0_0	Enter 4 Byte Address Mode trans- action sets the Address Legth bit CFR2V[7] to 1	1	B7 (CMD)	-	-	-	-	-	1	-	1			
	EX4BA_0_0	Exit 4 Byte Address Mode trans- action sets the Address Length bit CFR2V[7] to 0	-	B8 (CMD)	-	-	-	-	-	-	-	-			N/A
	RDDLP_0_0	Read Data Learning Pattern Register transaction reads the DLP pattern.	-	41 (CMD)	-	-	-	-	-	-	-	-	Figure 12		
	PRDLP_0_1	Program Data Learning Pattern transaction programs DLP pattern into the Nonvolatile registers	WRENB_0_0	43 (CMD)	Input DLP data [7:0]	-	-	-	-	-	-	-		166	
Register Access	WRDLP_0_1	Write Data Learning Pattern transaction writes DLP pattern into the Volatile register.	WRENB_0_0	4A (CMD)	Input DLP data [7:0]	-	-	-	-	-	-	-	Figure 11		
	WRAUB_0_1	AutoBoot Register Write transaction writes AutoBoot pattern into the register.	WRENB_0_0	15 (CMD)	Input Data 1 [7:0]	Input Data 2 [7:0]	(Continue)	-	-	-	-	-			
ECC	RDECC_C_0		-	19	ADDR [23:16]	ADDR [15:8]	ADDR [7:0]	-	-	-	-	-			3
	RDECC_C_0	Read ECC Status is used to determine the ECC status of the addressed data unit.	-	(CMD)	ADDR [31:24]	ADDR [23:16]	ADDR [15:8]	ADDR [7:0]	-	-	-	-	Figure 13		4
	RDECC_4_0		-	18 (CMD)	ADDR [31:24]	ADDR [23:16]	ADDR [15:8]	ADDR [7:0]	-	-	-	-			4
ECC	CLECC_0_0	Clear ECC Status Register trans- action resets ECC Status Register bit[4] (2-bit ECC Detection), ECC Status Register bit[3] (1-bit ECC Correction), Address Trap Register and ECC Detection Counter.	·	1B (CMD)	-	-	-	-	-	-	-	ı	Figure 7		N/A
CRC	DICHK_4_1	Data Integrity Check transaction causes the device to perform a Data Integrity Check over a user defined address range.	-	5B (CMD)	Start ADDR [31:24]	Start ADDR [23:16]	Start ADDR [15:8]	Start ADDR [7:0]	End ADDR [31:24]	End ADDR [23:16]	End ADDR [15:8]	EndADDR [7:0]	Figure 9		4

	PWDUL_0_1	Password Unlock transaction sends the 64-bit password to flash device. If the supplied password does not match the hidden password in the Password Register, the device is locked and only a hardware reset or POR will return the device to standby state, ready for new transactions such as a retry of the PWDUL_0_1. If the password does match, the PPB Lock bit is set to 1.	-	E9 (CMD)	Password [7:0]	Password [15:8]	Password [23:16]	Password [31:24]	Password [39:32]	Password [47:40]	Password [55:48]	Password [63:56]	Figure 35		N/A

Electrical characteristics 7

Absolute maximum ratings^[33, 34, 35] 7.1

Storage Temperature Plastic Packages......-65 °C to +150 °C Ambient Temperature with Power Applied......-65 °C to +125 °C

7.2 **Operating range**

Operating ranges define those limits between which the functionality of the device is guaranteed.

7.2.1 **Power supply voltages**

V _{CC} (HL-T Devices)	. 2.7V to 3.6V
V _{CC} (HS-T Devices)	. 1.7V to 2.0V

Temperature ranges^[36] 7.2.2

Table 78 **Temperature ranges**

Darameter	Svmbol	Devices	Sp	Spec		
Parameter	Syllibot	Devices	Min	Max	Unit	
		Industrial / Automotive AEC-Q100 Grade 3		+85	°C	
Ambient Temperature	T _A	Industrial Plus / Automotive AEC-Q100 Grade 2	-40	+105		
		Automotive AEC-Q100 Grade 1		+125		

^{36.} Industrial Plus, Automotive Grade-2 and Automotive Grade-1 operating and performance parameters will be determined by device characterization and may vary from standard industrial or Automotive Grade-3 temperature range devices as currently shown in this specification.

^{33.} See Input signal overshoot on page 106 for allowed maximums during signal transition.
34. No more than one output may be shorted to ground at a time. Duration of the short circuit should not be greater than one second.

^{35.} Stresses above those listed under Absolute maximum ratings[33, 34, 35] on page 104 may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational sections of this datasheet is not implied. Exposure of the device to absolute maximum rating conditions for extended periods may affect device reliability.

V _{CC} Current	-100	+100	mA

^{37.} Excludes power supply V_{CC} . Test conditions: $V_{CC} = 1.8V / 3.0V$, one connection at a time tested, connections not being tested are at V_{SS} .

Electrical characteristics

7.6 **DC** characteristics

Input signal overshoot 7.6.1

During DC conditions, input or I/O signals should remain equal to or between V_{SS} and V_{CC} . During voltage transitions, inputs or I/Os may overshoot V_{SS} to -1.0V or overshoot to V_{CC} +1.0V, for periods up to 20 ns.

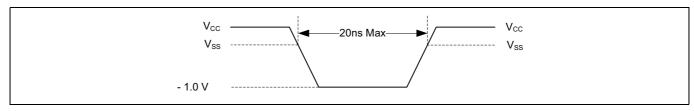

Figure 70 **Maximum negative overshoot waveform**

Notes

- 42. Output HI-Z is defined as the point where data is no longer driven.

42. Output HI-2 is defined as the point where data is no longer driven.
43. Applicable across all operating temperature options.
44. If Reset# is asserted during the end of t_{PU}, the device will remain in the reset state and t_{RH} will determine when CS# may go Low.
45. Sum of t_{RP} and t_{RH} must be equal to or greater than t_{RPH}.
46. Typical program and erase times assume the following conditions: 25°C, V_{CC} = 1.8V and 3.0V; checkerboard data pattern.
47. The programming time for any OTP programming transaction is the same as t_{PP}.
48. The programming time for the PRPPB_4_0 and PRPPB_C_0 transactions is the same as t_{PP}. The erase time for ERPPB_0_0 transaction is the same as

t_{SE}.
 49. Values are guaranteed by characterization and not 100% tested in production.
 50. Guaranteed by design.
 51. The Joint Electron Device Engineering Council (JEDEC) standard JESD22-A117 defines the procedural requirements for performing valid endurance and retention tests based on a qualification specification. This methodology is intended to determine the ability of a flash device to sustain repeated data changes without failure (program/erase endurance) and to retain data for the expected life (data retention). Endurance and retention qualification specifications are specified in JESD47 or may be developed using knowledge-based methods as in JESD94.

- 44. If Reset# is asserted during the end of t_{PLI}, the device will remain in the reset state and t_{RH} will determine when CS# may go Low.

^{45.} Sum of t_{RP} and t_{RH} must be equal to or greater than t_{RPH}.

46. Typical program and erase times assume the following conditions: 25°C, V_{CC} = 1.8V and 3.0V; checkerboard data pattern.

47. The programming time for any OTP programming transaction is the same as t_{PP}.

48. The programming time for the PRPPB_4_0 and PRPPB_C_0 transactions is the same as t_{PP}. The erase time for ERPPB_0_0 transaction is the same as

<sup>ts_E.
49. Values are guaranteed by characterization and not 100% tested in production.
50. Guaranteed by design.
51. The Joint Electron Device Engineering Council (JEDEC) standard JESD22-A117 defines the procedural requirements for performing valid endurance and retention tests based on a qualification specification. This methodology is intended to determine the ability of a flash device to sustain repeated data changes without failure (program/erase endurance) and to retain data for the expected life (data retention). Endurance and retention qualification specifications are specified in JESD47 or may be developed using knowledge-based methods as in JESD94.</sup>

9.1.2 **JEDEC SFDP Rev D parameter table**

For the SFDP data structure, there are three independent parameter tables. Two of the tables have a fixed length and one table has a variable structure and length depending on the device density Ordering Part Number (OPN). The Parameter table is presented as single table in Table 86.

Device identification

Sector Map Parameter Table Notes

Table 87 provides a means to identify how the device address map is configured and provides a sector map for each supported configuration. This is done by defining a sequence of commands to read out the relevant configuration register bits that affect the selection of an address map. When more than one configuration bit must be read, all the bits are concatenated into an index value that is used to select the current address map.

To identify the sector map configuration in device the following configuration bits are read in the following MSb to LSb order to form the configuration map index value:

- CFR3V[3] 0 = Hybrid Architecture, 1 = Uniform Architecture
- CFR1V[6] 0 = 4KB parameter grouped together, 1 = 4KB sectors split between bottom and top
- CFR1V[2] 0 = 4KB parameter sectors at bottom, 1 = 4KB sectors at top
- The value of some configuration bits may make other configuration bit values not relevant (don't care), hence
 not all possible combinations of the index value define valid address maps. Only selected configuration bit
 combinations are supported by the SFDP Sector Map Parameter Table (see Table 88). Other combinations must
 not be used in configuring the sector address map when using this SFDP parameter table to determine the sector
 map. The following index value combinations are supported.

Table 87 Sector map parameter

CFR3V[3]	CFR1V[6]	CFR1V[2]	Index value	Description
0	0	0	00h	4KB sectors at bottom with remainder 256KB sectors
0	0	1	01h	4KB sectors at top with remainder 256KB sectors
0	1	0	02h	4KB sectors split between top and bottom with remainder 256KB sectors
1	0	0	04h	Uniform 256KB sectors

11.2 Valid combinations — Automotive grade / AEC-Q100

Table 92 lists configurations that are Automotive Grade / AEC-Q100 qualified and are planned to be available in volume. The table will be updated as new combinations are released. Contact your local sales representative to confirm availability of specific combinations and to check on newly released combinations.

Production Part Approval Process (PPAP) support is only provided for AEC-Q100 grade products.

Products to be used in end-use applications that require ISO/TS-16949 compliance must be AEC-Q100 grade products in combination with PPAP. Non–AEC-Q100 grade products are not manufactured or documented in full compliance with ISO/TS-16949 requirements.

AEC-Q100 grade products are also offered without PPAP support for end-use applications that do not require ISO/TS-16949 compliance.

Revision history

Revision history

Document version	Date of release	Description of changes
*P	2019-06-04	Finalizing document for S25HS512T devices.
*Q	2019-06-21	Finalizing document for S25HL512T devices. Updated t _{VR} parameter. Introduced t _{VF} parameter.
*R	2019-07-03	Finalizing document for S25HL01GT devices. Updated I _{CC1} parameters. Updated Valid Combinations.
*S	2019-09-13	Updated Transaction table. Updated Ordering Information.
*T	2019-11-26	Finalizing document for S25HS01GT devices.
*U	2019-12-20	Updated Table 17, Table 85, and Table 87 (Product Information Notification).
*V	2019-01-29	Updated Table 73. Updated Sales information and Copyright year.
*W	2020-03-23	Updated Table 81 based on Final Characterization results.
*X	2020-04-22	Updated Table 9 , Table 48 , and Table 55 . Updated Table 85 and Table 87 (Product Information Notification).
*γ	2020-12-01	Updated text in Read QPI SDR and DDR transaction and Read QPI SDR and DDR transaction. Updated Related SPI Transaction for Configuration Register 4 to RDAY1_4_0 in Table 29. Updated text in Data learning pattern (DLP). Updated selection options for CFR3N[7:6], CFR3V[7:6] in Table 50. Added note in Table 56. Updated description and note for ASPO[2] in Table 58. Updated CFR3N[3], CFR1N[6], and CFR1N[2] to CFR3V[3], CFR1V[6], and CFR1V[2] in Sector Map Parameter Table Notes. Updated Sector Map Parameters in Table 86. Updated SFDP DWORD, Data, and Description in Table 87.
*Z	2021-10-18	Updated to Infineon template. Updated Table 79: Added Theta JB and JC and 256Mb packages. Updated Table 82: Added 256Mb specifications. Updated Table 84: Added 256Mb specifications. Updated Table 86: Added 256Mb specifications.
AA	2022-01-18	Updated Table 6: Changed JESD216C to JESD216D Changed CFR3V[1:0] to CFR3V[7:6] in Read device identification transaction Updated Table 84: Removed 256T / 512T / 01GT and updated max value for t _{PEDS} Updated Table 86: Updated data and description for 12Dh, 12Eh, and 12Fh byte addresses

IMPORTANT NOTICE

The information given in this document shall in no event be regarded as a guarantee of conditions or characteristics ("Beschaffenheitsgarantie").

With respect to any examples, hints or any typical values stated herein and/or any information regarding the application of the product, Infineon Technologies hereby disclaims any and all warranties and liabilities of any kind, including without limitation warranties of non-infringement of intellectual property rights of any third party.

In addition, any information given in this document is subject to customer's compliance with its obligations stated in this document and any applicable legal requirements, norms and standards concerning customer's products and any use of the product of Infineon Technologies in customer's applications.

The data contained in this document is exclusively intended for technically trained staff. It is the responsibility of customer's technical departments to evaluate the suitability of the product for the intended application and the completeness of the product information given in this document with respect to such application.

For further information on the product, technology, delivery terms and conditions and prices please contact your nearest Infineon Technologies office (www.infineon.com).

WARNINGS

Due to technical requirements products may contain dangerous substances. For information on the types in question please contact your nearest Infineon Technologies office.

Except as otherwise explicitly approved by Infineon Technologies in a written document signed by authorized representatives of Infineon Technologies, Infineon Technologies' products may not be used in any applications where a failure of the product or any consequences of the use thereof can reasonably be expected to result in personal injury.
